Supplement of

Impact of climate and land cover changes on tropospheric ozone air quality and public health in East Asia between 1980 and 2010

3 *S1. Detail land cover and land use data*

4 The Moderate Resolution Imaging Spectroradiometer (MODIS) satellite-derived
5 high-resolution land cover product for year 2010 is used as the baseline case in this work
6 (MCD12Q1) (https://lpdaac.usgs.gov/products/modis_products_table/mcd12q1). This
7 product includes five land cover classification schemes. Here we choose the
8 classification scheme of IGBP (International Geosphere-Biosphere Program) with 17
9 land cover types, including 13 vegetation classes (evergreen needleleaf forest, evergreen
10 broadleaf forest, deciduous needleleaf forest, deciduous broadleaf forest, mixed forest,
11 closed shrublands, open shrublands, woody savannas, savannas, grasslands, permanent
12 wetlands, croplands, cropland/natural vegetation mosaic) and 4 non-vegetated land types
13 (water, urban and built-up, snow and ice, barren or sparsely vegetated). We further
14 combine them with the Koppen main climate classes following Steinkamp and Lawrence
15 (2011). [As a result, a new land cover map MODIS-IGBP-Koppen in year 2010 with 23 land cover types is developed.](#) The distribution of land cover and land use types [in year 2010](#) used in this study are shown in Fig. S1.

18 To derived the land cover and land use in year 1980, we produce the potential land
19 cover map by integrating multiple sources of data and information, [including the MODIS-IGBP land cover data in 2005, the Koppen main climate classes map, the China National land cover dataset \(NLCD\) for the late 1980s and year 2005 \(Liu and Buheaosier, 2000; Liu et al., 2005a, b\), and the harmonized historical cropland and urban land use dataset from the historical land cover projects of Representative Concentrationthe Pathways \(RCPs\) for the period 1980-2005 from Hurtt et al.\(2011\).](#) To
25 ensure the self-consistency of the PFT across the period, we assume that the PFT
26 definition and the vegetation composition for each PFT remained unchanged. The
27 [MODIS-IGBP-Koppen land map in 2005 is developed through combining the MODIS-IGBP land cover data in 2005 with the Koppen main classes following the same methods of generating the MODIS-IGBP-Koppen land cover types in 2010.](#) The
29 reconstructed cropland and urban areas are based on the HYDE model which combines
30 numerous historical statistics, census data and satellite-derived current land cover from
31 DISCover 2 data (Loveland et al., 2000) and Global Land Cover (GLC 2000)
32 (Bartholome et al., 2002). The method we use to reconstruct the land cover and land use
33 in 1980 is similar to that of Liu and Tian (2010), and is based on the
34 MODIS-IGBP-Koppen LCLU in year 2005 as base year and applies appropriate
35 calibration ratios to scale up/down the 2005 data. For instance, cropland and urban
36 fractional coverage in year 1980 in each model grid cell is obtained by scaling up/down
37 the MODIS-IGBP-Koppen value in 2005 with a calibration ratio derived from the slope
38

39 of time-series linear regression of 1980-2005 harmonized RCP data. For each of the other
 40 natural vegetation types, the calibration ratio is an overall ratio derived from the slope of
 41 reduced major-axis regression between NLCD 1980s and NLCD 2005 available data
 42 over the whole spatial domain. It should be noted that the sum of fractional coverages of
 43 all PFTs including bareland of each grid cell is always constrained to unity.

45
 46 Fig. S1. Land cover and land use distribution in year 2010.
 47

48 *S2. Changes in biogenic VOC emissions*

49 Annual isoprene emission in East Asia decreases by 3% but increases by 2% in
50 China specifically as a result of LCLU change alone [between 1980 and 2010](#)
51 ($[CTRL]-[SIM_LCLU]$) (Table S4). Our calculated decreases (increases) in isoprene
52 emission in East Asia (China) generally agree with Stavrakou et al. (2014). Seasonal and
53 regional isoprene emission exhibits more pronounced changes in response to LCLU
54 change. In summer (JJA), we find that the seasonal mean isoprene emission increases
55 5-30% in central and southeastern China but decreases 5-20% over northeastern China,
56 Korea and Myanmar (Fig.2b). Changes in JJA isoprene emission are consistent in spatial
57 distribution with the changes in forest coverage (Fig. S2a). Increases in JJA isoprene
58 emission are likely caused by the enhanced fractional coverage of broadleaf and mixed
59 forests, while the reduction of isoprene emission results from the reduced coverage of
60 both needleleaf and broadleaf forests over those regions. In spring (MAM), LCLU
61 change alone reduces isoprene emission by as much as 40% in eastern China, Korea, and
62 Southeast Asia (Fig. 3b). Such a decrease is primarily driven by reduced LAI in most of
63 East Asia (Fig. 1b).

64 Climate change alone increases annual isoprene emission in East Asia by 7.4%
65 ($[CTRL]-[SIM_CLIM]$) (Table S4). In summer, isoprene emission increases by 5-20% in
66 most places of East Asia (Fig. S2b). In spring, isoprene emission increases by 5-40% in
67 southern China and parts of Southeast Asia, while isoprene emission in Myanmar,
68 northern China and Japan decreases by 5-30% due to climate change alone.

69

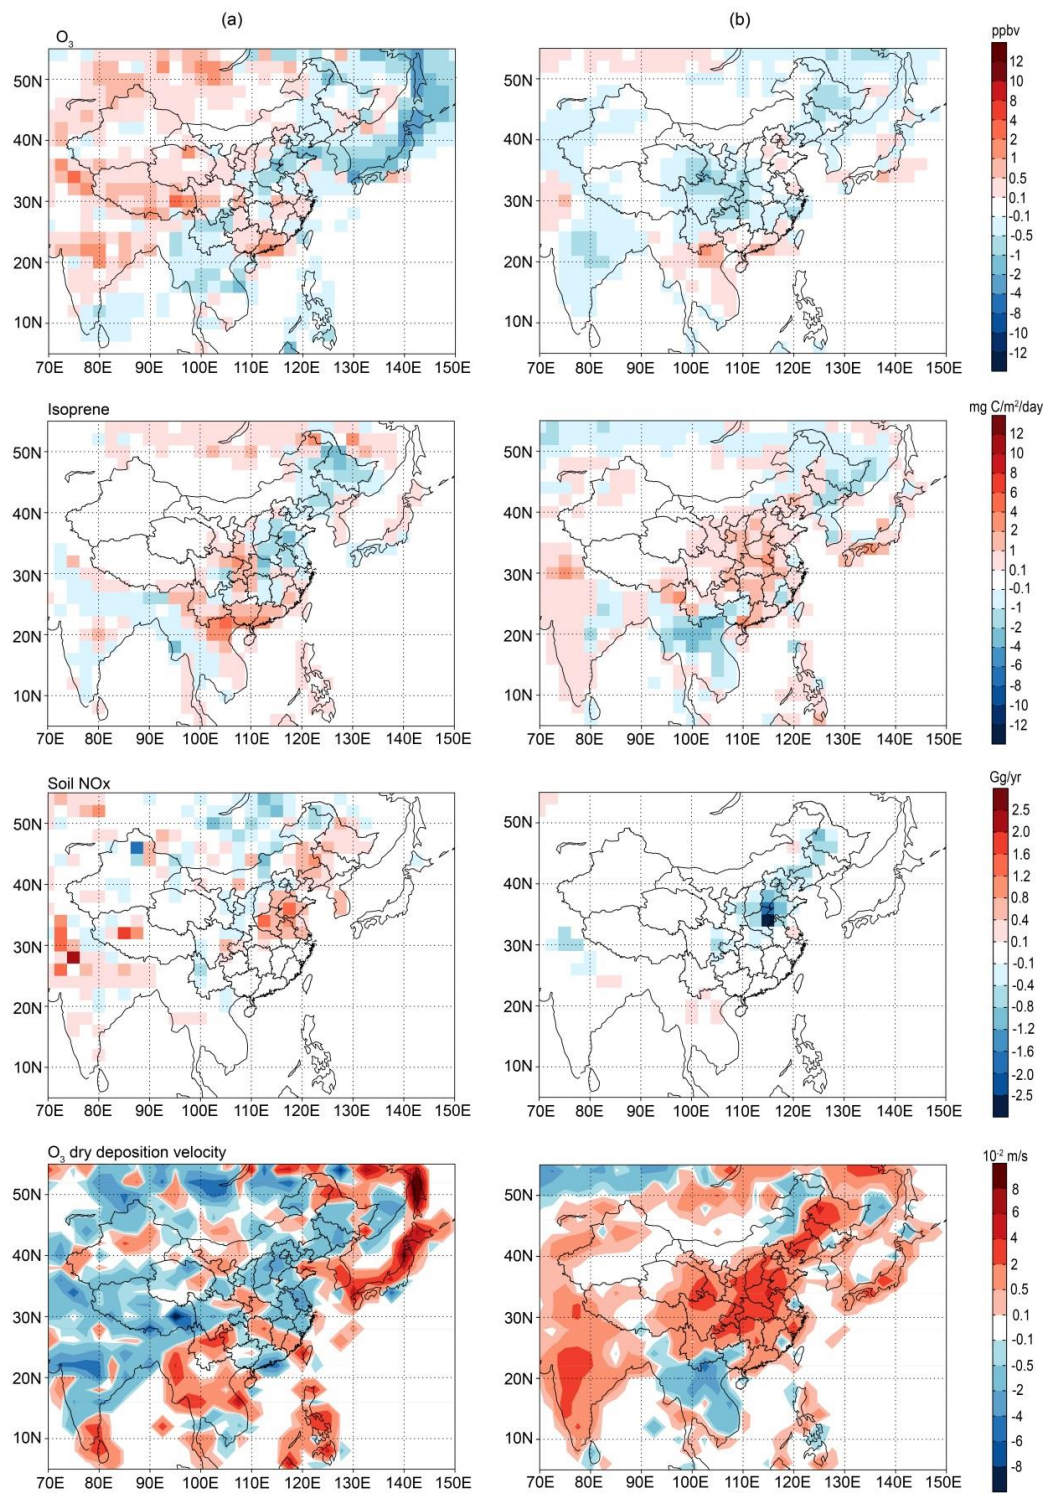

70

71 Fig. S2. Changes in (a) fractional coverage of broadleaf, needleleaf, and mixed forests;
72 and (b) in isoprene emission in summer (JJA) and spring (MAM) driven by climate
73 change alone [from the period 1981-1985 to the period 2007-2011](#).

89 *S5. Interannual variations of ozone concentration in simulation CTRL and COMB*

90

91

92 Fig. S5. Mean absolute deviation (MAD) of surface ozone in JJA and MAM from the
93 simulations CTRL (2007-2011) and the simulations COMB (1981-1985).

94

95

96 ***S6. Method for assessing the health impact due to ozone air quality***

97 Since there are very limited studies reporting long-term ozone-related mortality in
98 East Asia, we apply epidemiological concentration-response functions (CRFs) from
99 American Cancer Society (ACS) in this study. As in Anenberg et al (2010) and Silva et al
100 (2013), we use surface ozone concentrations to estimate excess ozone-related respiratory
101 mortality (ΔM , unit: 1000 deaths per year per squared km) by applying the following
102 CRFs (Anenberg et al., 2010):

103
$$\Delta M = y_0(1 - e^{-\beta\Delta X})P$$

104 where y_0 represents the baseline mortality rate (unit: deaths per thousand people per year),
105 β is a concentration-response factor, ΔX represents the differences in ozone
106 concentrations (April-September 6-month averaged of 1-h daily maximum ozone
107 concentration (Jerrett et al., 2009)), and P is the exposed population (unit: people per
108 squared km). Consistent with ACS, we only assess ozone-related health impact for all
109 adults aged 30 and above. We use gridded population of the world at approximately
110 $0.5^\circ \times 0.5^\circ$ resolution from Socioeconomic Data and Applications Center (SEDAC),
111 Columbia University (version 3 for future estimates in year 2010;
112 <http://sedac.ciesin.columbia.edu/data/set/gpw-v3-population-density-future-estimates>,
113 accessed by 7 November 2014) and United Nations estimates of 2010 population by
114 age-group per country (World Population Prospects, 2012 revision,
115 <http://esa.un.org/unpd/wpp/Excel-Data/population.htm>, accessed by 7 November 2014)
116 to calculate the fraction of population aged 30 and above at the country level and the
117 exposed population aged 30 and above in East Asia. Then, the exposed population over
118 30 is regridded to $2^\circ \times 2.5^\circ$ resolution consistent with that of the simulated ozone
119 concentrations.

120 Baseline mortality rates for respiratory disease are calculated from the World Health
121 Organization 2000-2012 country-level cause-specific mortality for population aged 30 or
122 above (http://www.who.int/healthinfo/global_burden_disease/estimates/en/index1.html,
123 accessed by 7 November 2014). The concentration-response factor is derived from
124 relative risks (RR) estimated in long-term epidemiological studies, which is represented
125 as a log-linear relationship between ozone concentration and RR ($\beta = \ln(\text{RR})/10$) (Jerrett
126 et al., 2009).

127

128

129

130

Table S1. PFT-specific emission factors* for biogenic VOC emissions used in this study (units: $\mu\text{g m}^{-2} \text{h}^{-1}$).

PFTs	Compound Class	Isoprene	Monoterpenes						MBO	Acetone	
			α -Pinene	β -Pinene	Myrcene	Sabinene	Limonene	3-Carene			Ocimene
Evergreen broadleaf forest (<i>warm temperate; snow; polar</i>)		10000	400	130	30	50	80	30	120	0.01	240
Deciduous broadleaf forest (<i>warm temperate; snow; polar</i>)		10000	400	130	30	50	80	30	120	0.01	240
Deciduous needleleaf forest		1	510	200	60	40	130	80	60	0.01	240
Evergreen needleleaf forest		3000	500	300	70	70	100	160	70	60	240
Deciduous broadleaf forest (<i>equatorial; arid</i>)		7000	600	120	80	80	80	40	150	0.01	240
Evergreen broadleaf forest (<i>equatorial; arid</i>)		7000	600	120	80	80	80	40	150	0.01	240
Closed shrubland		4000	200	100	30	50	60	30	90	0.01	240
Open shrubland (<i>equatorial; arid; warm temperate</i>)		2000	200	100	30	50	60	30	90	0.01	240
Open shrubland (<i>snow; polar</i>)		2000	200	100	30	50	60	30	90	0.01	240
Grassland (<i>snow; polar</i>)		1600	2	1.5	0.3	0.7	0.7	0.3	2	0.01	80
Savannah (<i>snow; polar</i>)		1600	2	1.5	0.3	0.7	0.7	0.3	2	0.01	80
Savannah (<i>equatorial; arid; warm temperate</i>)		800	2	1.5	0.3	0.7	0.7	0.3	2	0.01	80
Grassland (<i>equatorial; arid; warm temperate</i>)		800	2	1.5	0.3	0.7	0.7	0.3	2	0.01	80
Woody savannah		4000	300	150	50	70	100	100	150	0.01	240
Cropland		1	2	1.5	0.3	0.7	0.7	0.3	2	0.01	80
Mixed forest	Assumed the coverage are equally divided into 4 types of broadleaf trees and 2 types of needleleaf trees										
Cropland/natural vegetation mosaic	Assumed the coverage are divided into cropland (40%), shrubland (30%) and grassland (30%)										

* Guenther et al. (2012)

Table S2. Method for merging 23 land types into 5 MEGAN PFTs.

No.	MODIS_Koppen land type	MEGAN PFT
1	Water	-
2	Permanent wetland	-
3	Snow and ice	-
4	Barren (snow; polar)	-
5	Unclassified	-
6	Barren (equatorial; arid; warm temperate)	-
7	Closed shrubland	Shrub
8	Open shrubland (equatorial; arid; warm temperate)	Shrub
9	Open shrubland (snow; polar)	Shrub
10	Grassland (snow; polar)	Grass
11	Savannah (snow; polar)	Grass
12	Savannah (equatorial; arid; warm temperate)	Grass
13	Grassland (equatorial; arid; warm temperate)	Grass
14	Woody savannah	Shrub
15	Mixed forest	Assume Mixed forest consist of 30% broadleaf trees and 70% needleleaf trees
16	Evergreen broadleaf forest (warm temperate; snow; polar)	Broadleaf trees
17	Deciduous broadleaf forest (warm temperate; snow; polar)	Broadleaf trees
18	Deciduous needleleaf forest	Needleleaf trees
19	Evergreen needleleaf forest	Needleleaf trees
20	Deciduous broadleaf forest (equatorial; arid)	Broadleaf trees
21	Evergreen broadleaf forest (equatorial; arid)	Broadleaf trees
22	Cropland	Crop
23	Urban and built-up lands	-
24	Cropland/natural vegetation mosaic	Assume this type composes of 40% crop, 30% shrub and 30% grass.

Table S3. Mapping 23 land types into Olson land types used for dry deposition.

NO	MODIS_Koppen land types	Olson ID	Olson land types*
1	Water	0	water
2	Permanent wetland	45	wetland
3	Snow and ice	17	Ice
4	Barren (snow; polar)	53	Barren tundra
5	unclassified	-	Not used
6	Barren (equatorial; arid; warm temperate)	8	Desert
7	Closed shrubland	47	Shrub
8	Open shrubland (equatorial; arid; warm temperate)	47	Shrub
9	Open shrubland (snow; polar)	42	Shrub/grass (cold)
10	Grassland (snow; polar)	40	Shrub/grass (cool)
11	Savannah (snow; polar)	40	Shrub/grass (cool)
12	Savannah (equatorial; arid; warm temperate)	-	-
13	Grassland (equatorial; arid; warm temperate)	41	Shrub/grass (hot and mild)
14	Woody savannah	32	Dry tropical woods
15	Mixed forest	24	Mixed forest
16	Evergreen broadleaf forest (warm temperate; snow; polar)	25	Cool broadleaf forest
17	Deciduous broadleaf forest (warm temperate; snow; polar)	25	Cool broadleaf forest
18	Deciduous needleleaf forest	21	Conifer boreal forest
19	Evergreen needleleaf forest	22	Conifer
20	Deciduous broadleaf forest (equatorial; arid)	29	Tropical broadleaf
21	Evergreen broadleaf forest (equatorial; arid)	29	Tropical broadleaf
22	Cropland	31	Agricultural
23	Urban and build-up lands	1	Urban
24	Cropland/natural vegetation mosaic	57	Mixed wood/open

* 74 Olson land types are further corresponding to 11 surface types for calculating dry deposition in GEOS-Chem model (Wesely, 1989; Olson, 1992; Jacob et al., 1990, 1992; Wang et al., 1998)

Table S4. Simulated changes in biogenic hydrocarbon emission and soil NO_x emission due to LCLU change, climate change, and combined climate and LCLU change in East Asia. The domain of East Asia is 5.5 °-56.0 °N, 69.0 °-149.0 °E.

Species	CTRL	SIM_LCLU (changes, %)	SIM_CLIM (changes, %)	SIM_COMB (changes, %)
Biogenic hydrocarbons (Tg C yr⁻¹)				
Isoprene	34.700	35.635(-2.6)	32.316 (+7.4)	33.271 (+4.3)
Monoterpenes	9.389	9.370 (+0.2)	8.859 (+6.0)	8.855 (+6.0)
Methyl Butenol	0.239	0.241 (-0.7)	0.216 (+11.0)*	0.218 (+9.8)*
Farnesene	0.240	0.252 (-4.8)	0.225 (+6.9)	0.239 (+0.7)
b-Caryophyllene	0.326	0.339 (-3.8)	0.304 (+7.5)	0.320 (+2.2)
Other sesquiterpenes	0.659	0.687 (-4.0)	0.614 (+7.4)	0.650 (+1.9)
Other monoterpenes	1.509	1.482 (+1.8)	1.413 (+6.8)	1.393 (+8.3)
Acetone	5.116	5.173 (-1.1)	4.920 (+4.0)	4.979 (+2.7)
PRPE (lumped >= C3 alkenes)	0.992	1.019 (-2.6)	0.924 (+7.4)	0.952 (+4.3)
Total	53.172	54.199 (-1.9)	49.790 (+6.8)	50.873 (+4.5)
NO_x (Tg N yr⁻¹)				
Soil NO _x	2.067	2.053 (+0.7)	2.019 (+2.4)	2.000 (+3.3)
Fertilizer NO _x	0.742	0.741 (+0.1)	0.771 (-3.9)	0.771 (-3.9)
Ozone burden (Tg) (up to 2 km)				
Annual mean in EA	5.638	5.642(-0.071)	5.609(+0.52)	5.615(+0.41)
Summer mean in EA	5.946	5.961(-0.25)	5.795(+2.61)	5.809(+2.36)
