Supplement of

Long-range and local air pollution: what can we learn from chemical speciation of particulate matter at paired sites?

Marco Pandolfi et al.

Table S6: Main features of the sources from both the single-site PMF and the multi-site PMF (shaded background) for each country. EV: explained variation of the main markers of the sources for each PMF run; K: ratios between specific tracers in each source profile; CV: coefficient of variation of the ratios for each source. Ratio: ratios used to calculate K. CV values above 25% are highlighted in bold.

Source	Country	Paired sites	base run EV	K	CV [%] (a)	Ratio

(**) Mixed with SSA in the single MSA PMF.

- **Source profiles from multi-site PMF for Spain.**

Figure S1 shows the chemical profiles of the sources detected at BCN, MSY and MSA from the multi-site PMF. A total of 7 common sources were identified at the three sites, namely:

- *Heavy-Oil combustion (V-Ni)*, traced mainly by V, Ni and SO_4^{2-} and representing the direct emissions from heavy oil combustion sources, mostly shipping in the area under study during the period considered, but also long range transport. The sulfate associated with this source also includes primary sulfate from shipping (Ref.)

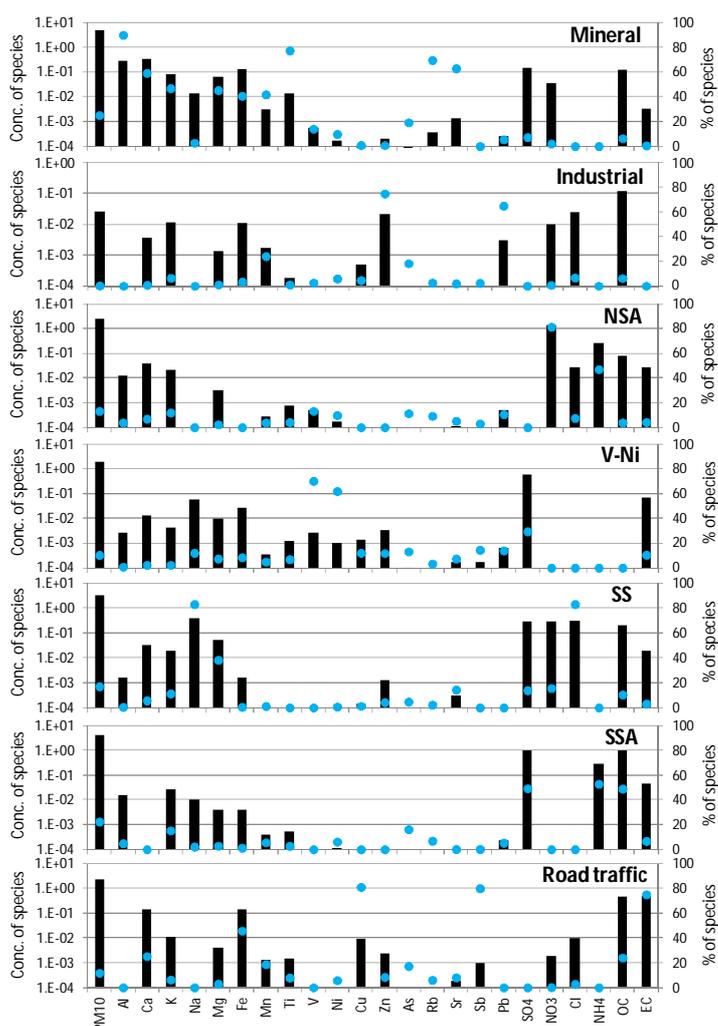

Figure S1: Chemical profiles of the sources detected at Barcelona (BCN; UB), Montseny (MSY; RB) and Montsec (MSA; CB) (Spain).

- *Mineral (MM)*, traced by typical crustal elements such as Al, Ca, Ti, Rb, and Sr;
- *Aged sea salt (SS)*, traced by Na and Cl mainly with contributions from SO_4^{2-} and NO_3^- suggesting some aging of marine aerosols;
- *Secondary sulfate (SSA)*, secondary inorganic source traced by SO_4^{2-} and NH_4^+ with relatively high contents of OC which have been attributed to the condensation

of semi-volatile compounds on the high specific surface area of ammonium sulfate particles (Amato et al., 2009);

- *Primary Industrial (IND)*, traced by Pb and As representing mostly emissions from metallurgy;
- *Primary Road Traffic (RT)*, traced mainly by EC, OC, Cu, Sb and Fe;
- *Secondary nitrate (NSA)*, secondary inorganic source traced by NO_3^- and NH_4^+ .

- **Source profiles from multi-site PMF for Switzerland.**

Figure S2 shows the chemical profiles of the sources from multi-site PMF for Switzerland. A total of 6 sources were identified at the two sites. A description of the sources is given below. The number and type of sources is the same as in Gianini et al. (2012):

- *Primary Road Traffic (RT)*, explaining large fractions of EC, OC and of the road traffic related elements (Mn, Cr, Fe, Cu, Mo, Sb);

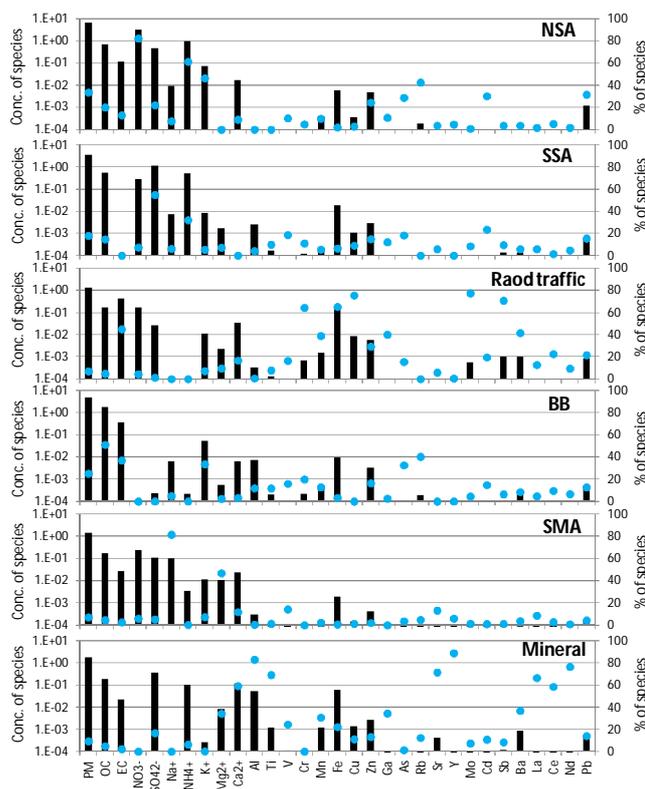

Figure S2: Chemical profiles of the sources detected at Zurich-Kaserne (ZUE; UB) and Payerne (PAY; RB).

- *Mineral (MM)*, dominated by Ca^{2+} , Fe, Al and Mg^{2+} , representing the main components of crustal matter. The mineral dust factors account moreover for a large mass fraction of crustal elements such as Ti, Sr, Y, La, Ce and Nd;
- *Na-Mg rich (SS)*, contributing to high fractions of Na^+ and Mg^{2+} . The contributions of the *Na-Mg rich* factor did not show a clear annual cycle with elevated values during winter, thus suggesting a low contribution from the de-icing road salt. This

source was mostly related to the transport of sea spray aerosol particles (Gianini et al., 2012).

- *Secondary sulfate (SSA)*, characterized by high concentrations of SO_4^{2-} and NH_4^+ . Moreover, a relevant fraction of measured OC is also explained by the SSA factors; secondary OC is expected to be in receptor modelling studies largely associated with the secondary SO_4^{2-} because of similar temporal variation of these constituents of atmospheric PM (Kim et al., 2003). Relatively high contents of OC in secondary sulfate factors have been attributed to the condensation of semi-volatile compounds on the high specific surface area of ammonium sulfate (Amato et al., 2009);
- *Secondary nitrate (NSA)*, secondary inorganic source traced by NO_3^- and NH_4^+ ;
- *Biomass burning (BB)*, traced by high concentrations of OC, EC and K^+ . This factor also explains a relevant mass fraction of Rb, an element related to biomass combustion emissions (Godoy et al., 2005);

- **Source profiles from multi-site PMF for France.**

Figure S3 shows the chemical profiles of the sources from multi-site PMF for France. A total of 9 sources were identified at the French paired sites. A description of the sources is given below.

- *Fresh sea salt*, traced by Na^+ and Cl^- this source represents mainly fresh marine aerosols;
- *Land (or Primary) biogenic (LB)*, traced by alcohols (arabitol and mannitol);
- *Secondary sulfate (SSA)*, secondary inorganic aerosol traced by SO_4^{2-} and NH_4^+ ;
- *Primary Road traffic (RT)*, traced by EC, OC, Fe, Cu, Sb;
- *Biomass burning (BB)*, traced mostly by levoglucosan and polysaccharides;
- *Secondary nitrate (NSA)*, secondary inorganic aerosol traced by NO_3^- and NH_4^+ ;
- *Aged sea salt (SS)*, representing aged sea salt. Lack of Cl^- in the chemical profiles and presence of Na^+ and NO_3^- ;
- *Mineral (MM)*, traced mainly by typical crustal elements such as Fe, Ca, Al, Sr and Ti;
- *Marine biogenic (MB)*, traced mainly by methane sulphonic acid, a product of DMS oxidation.

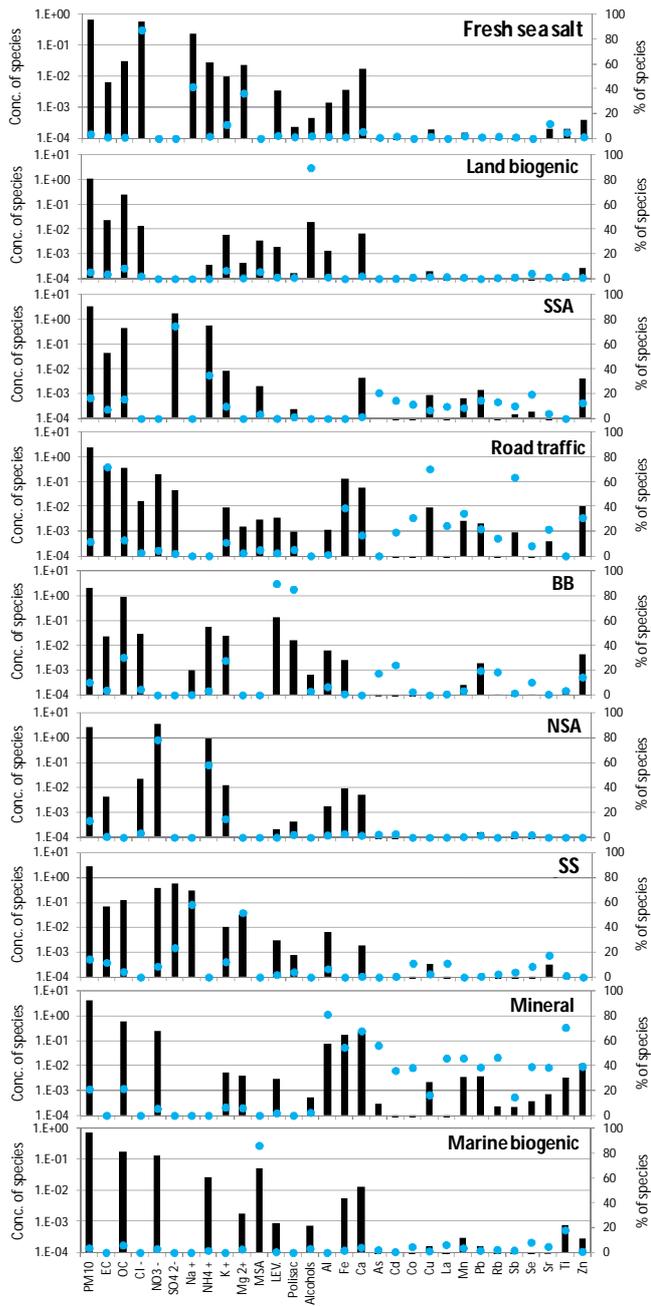

Figure S3: Chemical profiles of the sources detected at Lens (LENS; UB) and Revin (REV; RB).

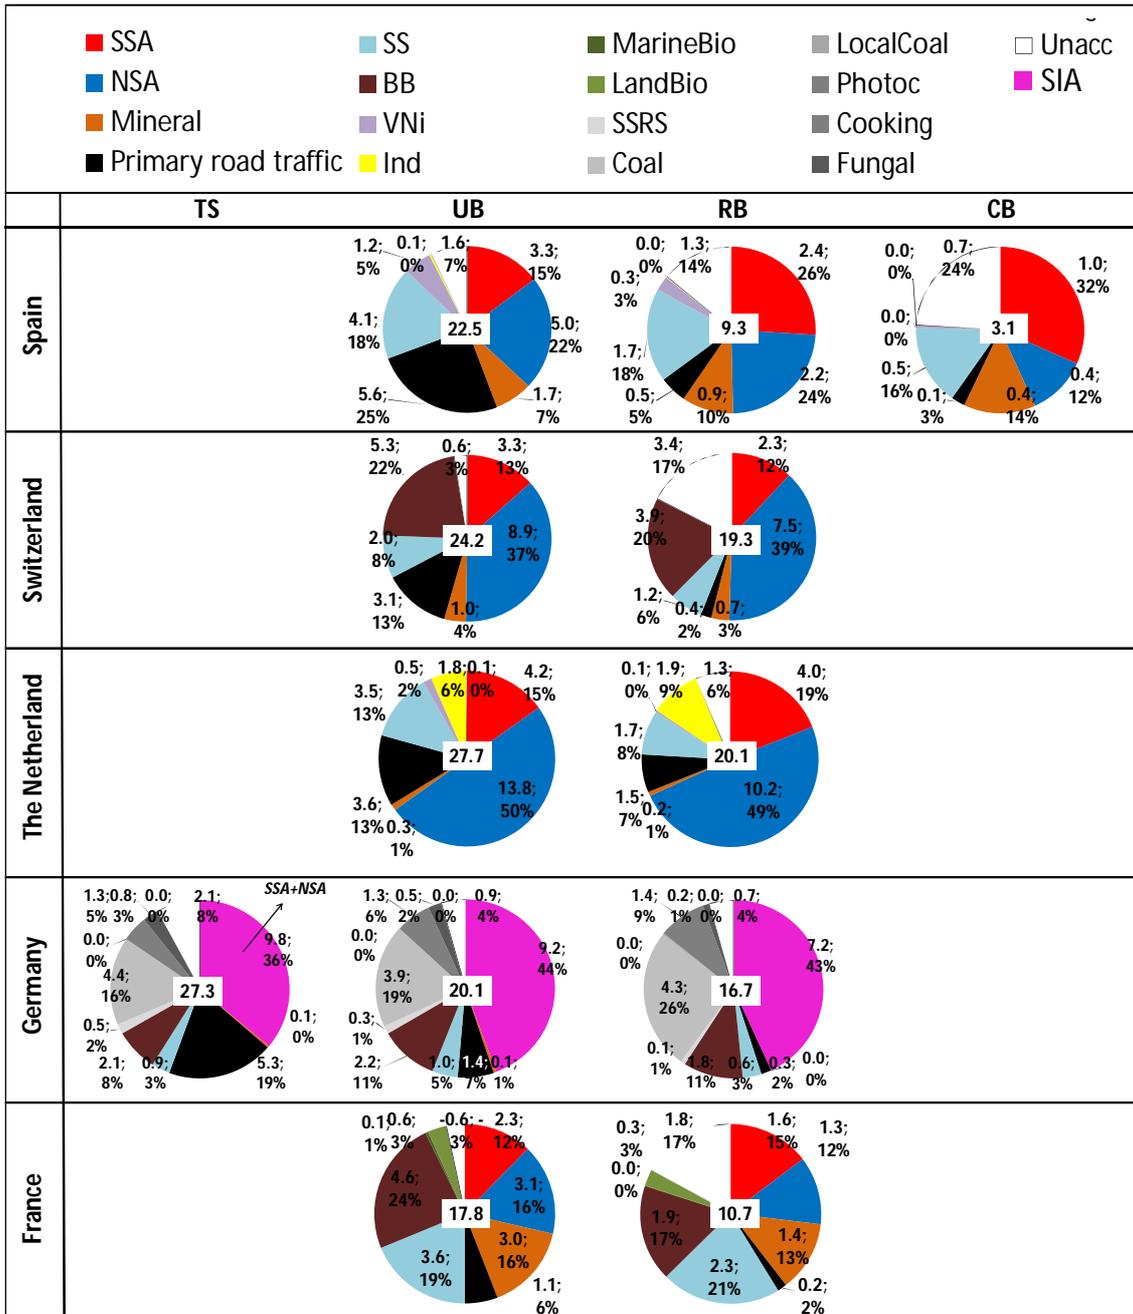

Figure S4: Source contributions to PM₁₀ (PM_{2.5} for The Netherlands) in winter (DJF) from the multi-site PMF for each country. The number in the white box at the center of the pie chart is the measured mass of PM (in μg/m³). TS: traffic site; UB: urban background; RB: regional background; CB: continental background.

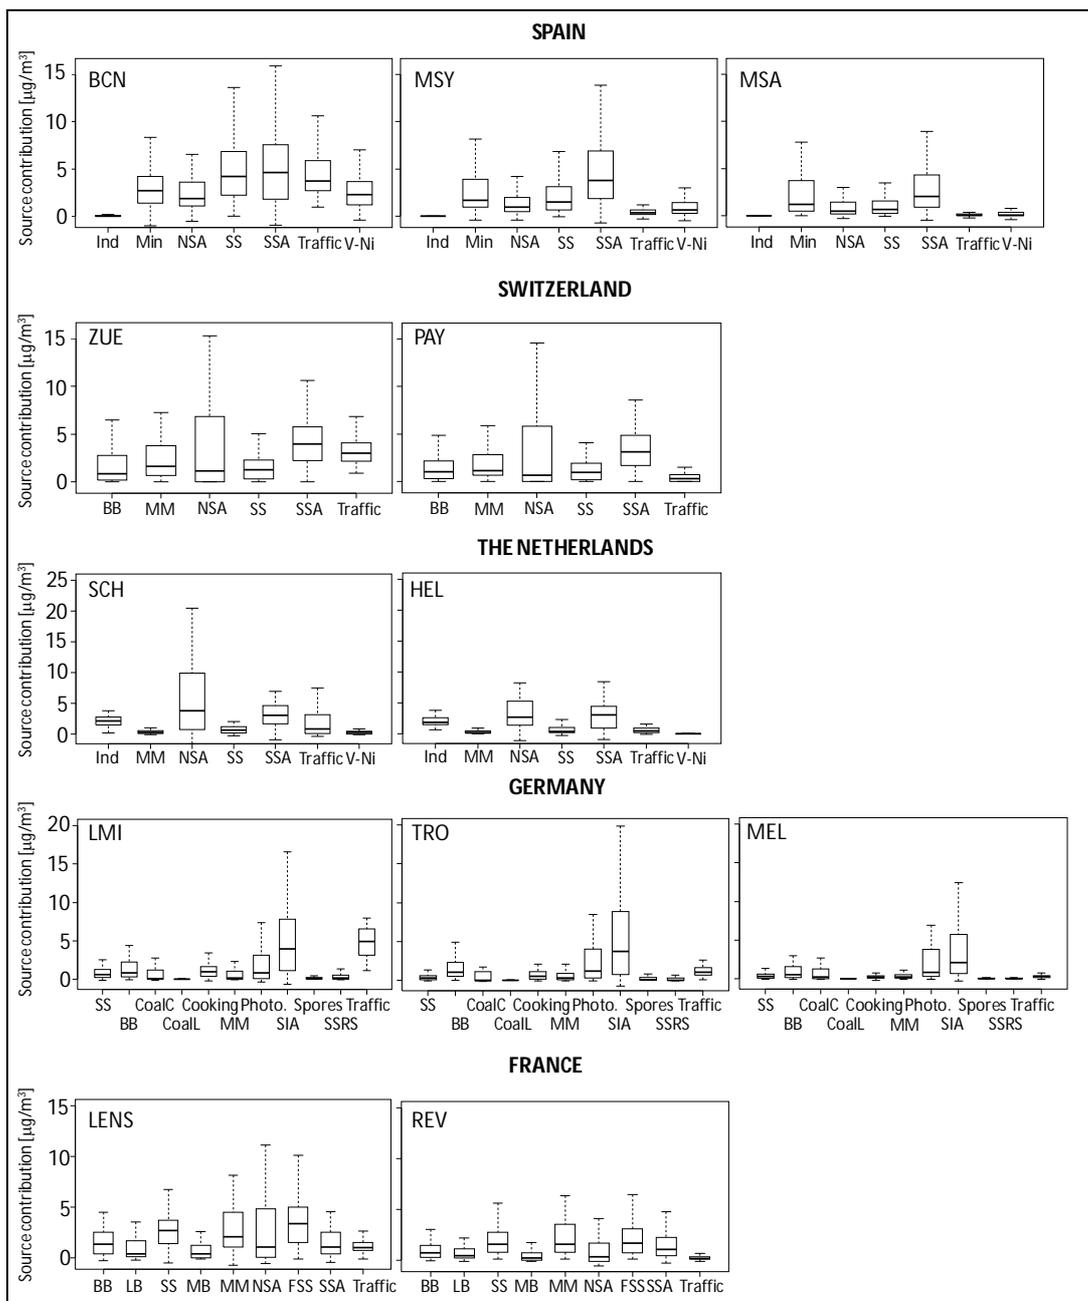

Figure S6: Mean annual source contributions to PM₁₀ (PM_{2.5} for The Netherlands) from the multi-site PMF for each site and country. IND: Industrial; MM: Mineral matter; NSA: nitrate-rich particles; SS: Aged sea Salt; SSA: sulfate-rich particles; RT: Road traffic; V-Ni: Residual oil combustion; BB: Biomass burning; Photo: Photochemistry; CoalL: Coal local; SIA: Secondary inorganic aerosols; SSRS: Sea salt/Road dust; LB: Land biogenic; FSS: Fresh sea salt; MB: Marine biogenic.

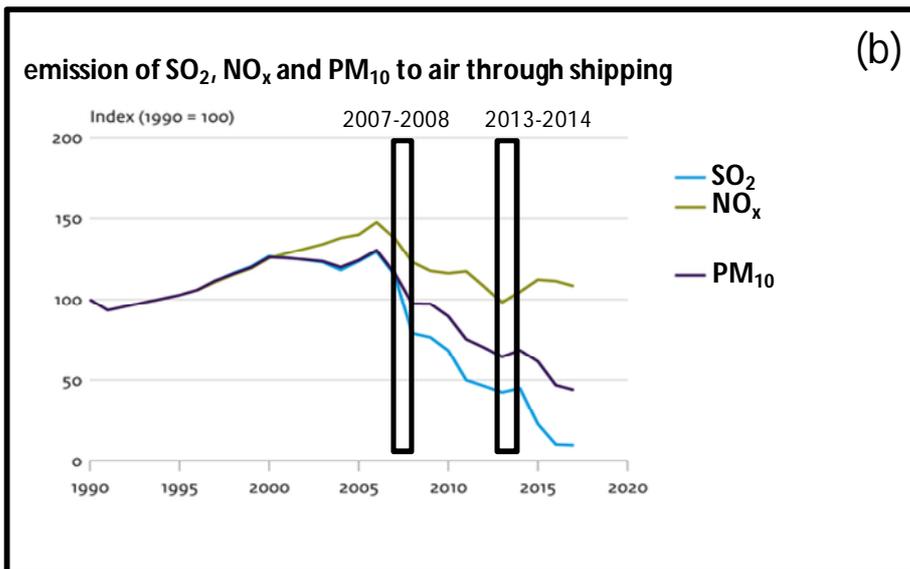

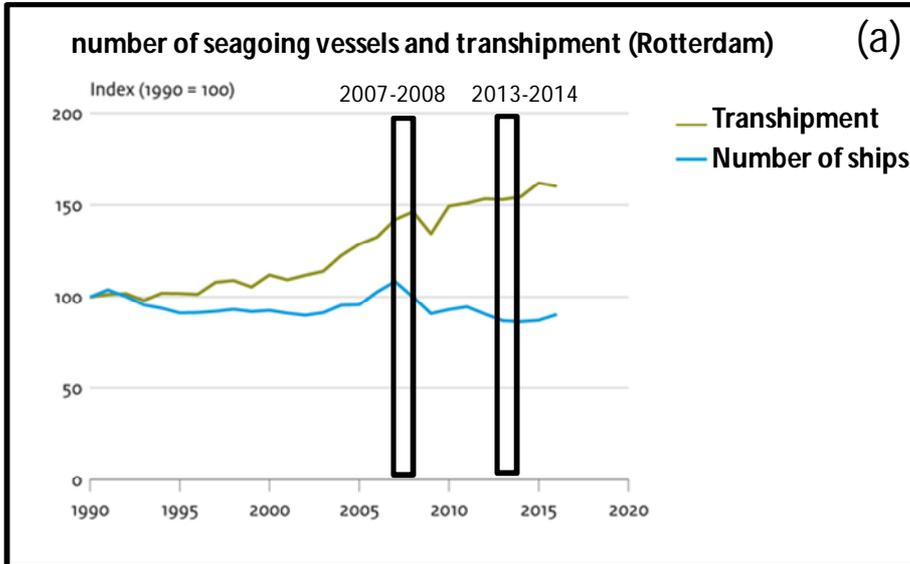

Figure S7: Number of seagoing vessels in Rotterdam (a), and emissions of SO₂, NO_x and PM₁₀ through maritime shipping (b) from 1990 to 2017 (adapted from Environmental Data Compendium, Government of the Netherlands, <https://www.clo.nl/en>.)

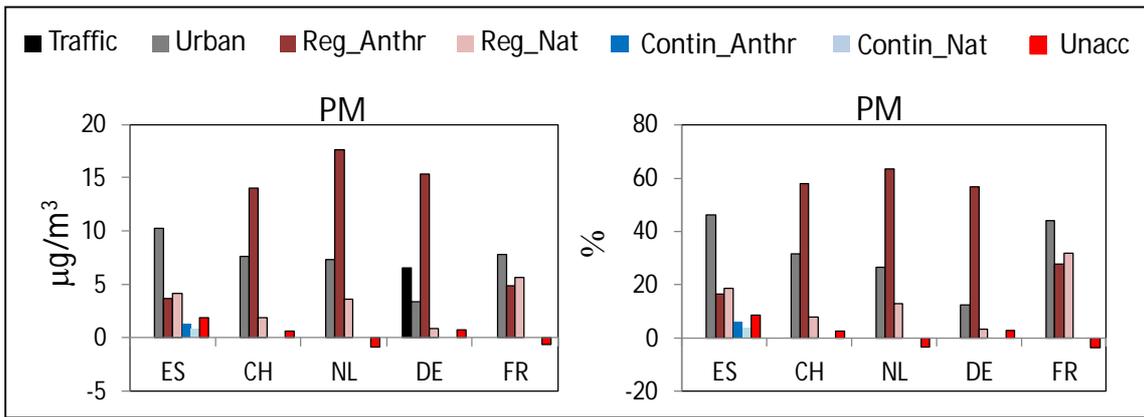

Figure S8: Lenschow's approach applied to the concentrations of PM. Average values for winter (DJF) are reported. ES: Spain; CH: Switzerland; NL: The Netherlands; DE: Germany; FR: France. In all countries with the exception of Spain, Reg_Anthr and Reg_Nat are the sum of regional+continental.

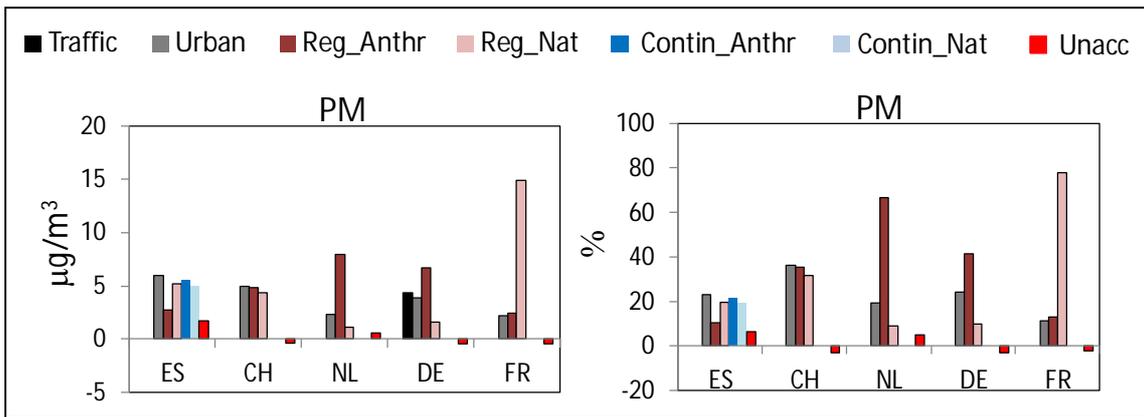

Figure S9: Lenschow's approach applied to the concentrations of PM. Average values for summer (JJA) are reported. ES: Spain; CH: Switzerland; NL: The Netherlands; DE: Germany; FR: France. In all countries with the exception of Spain, Reg_Anthr and Reg_Nat are the sum of regional+continental.

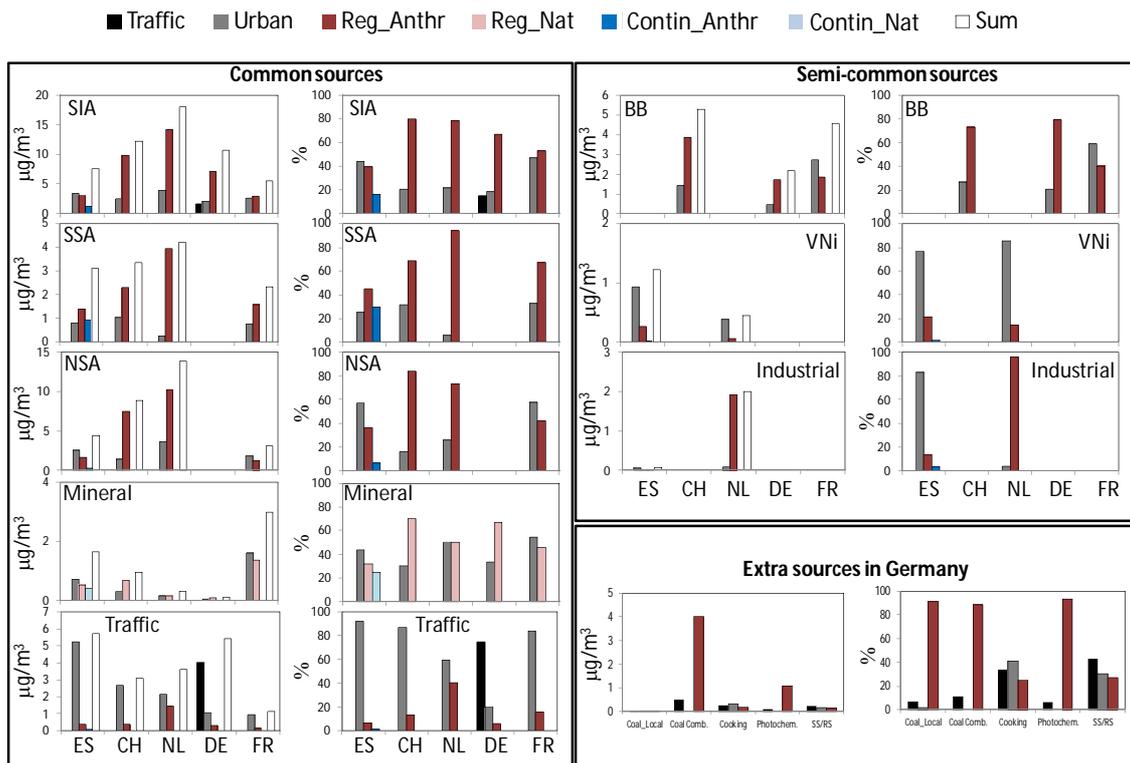

Figure S10: Lenschow's approach applied to the PMF source contributions. Average values for winter (DJF) are reported. ES: Spain; CH: Switzerland; NL: The Netherlands; DL: Germany; FR: France. In all countries with the exception of Spain, Reg_Anthr and Reg_Nat are the sum of regional+continental.

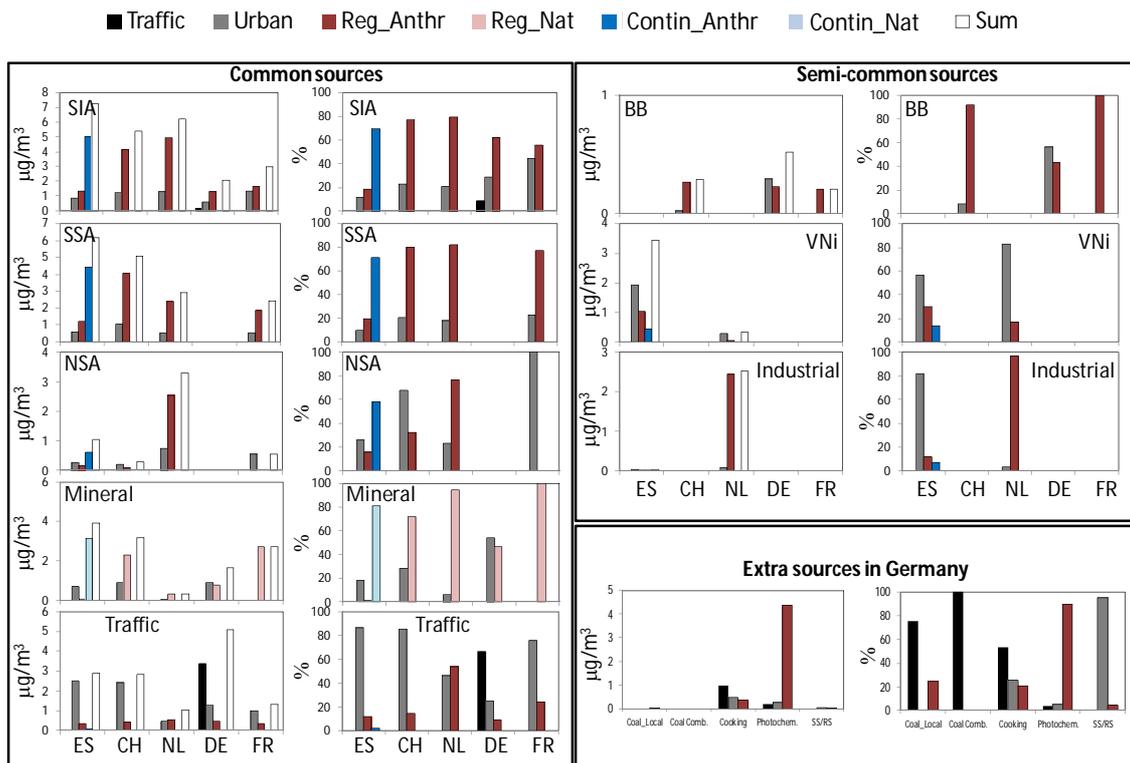

Figure S11: Lenschow's approach applied to the PMF source contributions. Average values for summer (JJA) are reported. ES: Spain; CH: Switzerland; NL: The Netherlands; DL: Germany; FR: France. In all countries, with the exception of Spain, Reg_Anthr and Reg_Nat are the sum of regional+continental.

Table S7: Allocation of PM to different sources and origin in each country. Annual means and winter (DJF) and summer (JJA) averages are reported.
