1. - INTRODUCTION

Du musst versthen!
Aus Eins mach zehn,
Und Zwei lass gehn,
Und Drei mach gleich,
So bist du reich.
Verlier die Vier!
Aus Fünf und Sechs -
So sagt die Hex -
Mach ists vollbracht:
Und Neun ist Eins,
Und Zehn ist Keins.
Das ist das Hexen - Einmaleins! /1/

It is getting more and more difficult for reactor physicists and designers to identify the hidden "sigillum Saturni" in the huge collections of data for neutronics calculations which pile-up year after year. Thus, there is strong necessity of both frequent critical revisions of the work already done and simply defined up-datings, as far as possible in the framework of standard processing procedures.

In this report we will be mainly concerned with revisions and up-datings, based on ENDF/B version 3, of fast reactor neutron cross sections libraries in the so-called "Bondarenko" format /2/.

As a background for the present work a number of basic choices were outlined in a review report /3/, and reference to previous work details can be found in /4/.

To summarize the present situation we can briefly recall:

a) the ENDF/B data and file format were generally adopted at CNEN /3/;

b) it was suggested /3/ a methodology of coupled use of both the ultrafine groups /5/ and the self-shielding factors /2/ philosophies;

c) a number of codes were implemented and in particular the ETOX-1DX /6, 7/ codes system (see paragraph 2), for handling the Bondarenko format;

d) for the best use of the methodology mentioned in b), a common energy group structure was adopted, based on half lethargy widths, for both libraries based or on self-shielding factors or ultrafine groups;

e) cross section adjustments in the energy structure adopted and for the most recent ENDF/B data, were derived for a few relevant isotopes from a correlation with high-accuracy benchmark integral experiments (see paragraph 3);

f) the interfaces previously developed /4/ with neutronics codes are still used, but a new code (1DX) is introduced to process cross section data, beside the PRAVDA code /8/.

2. - USE OF THE ETOX CODE AND THE GENERATION OF MULTIGROUP CROSS SECTIONS.

A number of minor modifications were necessary to run successfully the ETOX-3 code /7/. The modifications are mainly related to the increased dimension of version 3 of ENDF/B with respect to previous versions. In particular, the U-235 resolved resonances data and the number of points for the iron σ_t required special treatment. Other modifications are related to the possibility of dealing with the multilevel Breit-Wigner formalism.

The following ENDF/B version 3 materials were processed: U-234, U-235, U-238, Pu-239, Pu-240, Pu-241, Pu-242, Mo-98, Ta-181, Ta-182, Cu, Mn-55, Fe, Cr, Al-27, Na-23, O-16, C-12, B-10, B-11, Au-197. In the same collection, it was thought necessary to include Fe, Cr, Ni derived from ENDF/B version 1, in view of the unsatisfactory results so far obtain with the corresponding version 3 materials /9/.

Self-shielding factors were generated corresponding to the following values of the potential cross section: .01 b, 10 b, 100 b and 1000 b. Temperature T dependence was introduced considering 3 values of T: 300 K, 900 K and 2100 K.

Both infinite dilution cross sections and self-shielding factors were generated in the multigroup energy structure given in Table I, based on half-lethargy widths. The same multigroup structure was used in all the calculations in which the ultra-

fine group methodology was used as it is indicated in a companion report, dealing with such methodology /10/. The use of this multigroup structure prevents further use of the original ABBN library or KFK data /4/. On the other side, the completness of the ENDF/B files will provide the necessary replacements. Tables for all the materials are given in Appendix I.

3. - ADJUSTED CROSS SECTIONS.

Correlation between integral experimental data and multigroup cross sections has become a routine way to "up-date" neutron cross sections libraries in many leading Fast Reactor Programs abroad (UK, France, Japan). From our side, we used the integral benchmark experiments performed in ZPR-6 Assembly 7 and in SNEAK Assemblies 7A and 7B to adjust some of the previously mentioned materials derived from ENDF/B version 3. In particular K_{eff} and clean reaction rates ratios (^{238}U captures to ^{239}Pu fissions, ^{238}U fissions to ^{239}Pu fissions and ^{235}U fissions to ^{239}Pu fissions) experiments performed in the three assemblies were used to adjust the ^{238}U σ_c, σ_f and σ_{in}, the ^{239}Pu σ_f and fission spectrum, and the ^{235}U fission cross section /11/. The main trends of the adjustments are well justified if compared with recent independent evaluations. Moreover if we consider the following sequence of successive steps:

a) Use of ENDF/B version 1 (released 1970);
b) Adjustments of ENDF/B-1 with ZPR-6 Assembly 7 experimental results (1971-1972) /12, 4/;
c) Use of ENDF/B version 3 (released 1972);
d) Adjustments of ENDF/B-3 with ZPR-6 and SNEAK experimental results (1973) /11/,

we have an increasing number of consistent informations exploit-

ed in an optimal way. In fact, from step a) to b), consistency was gained with a series of highly reliable experiments. However, since the basic data were sometimes rather unsatisfactory (e.g. $^{239}Pu\ \alpha$ and $^{235}U\ \sigma_f$), the adjustments too could be questioned.

With step c) , new and more accurate data were introduced in the basic data collection. It is interesting to note that the data of step b) already indicated, independently, the trends of the new data of step c) /12/. A higher degree of sophistication and, hopefully, of confidence, was reached with step d), when new benchmark integral data were taken into account and using a more accurate set of basic data as a starting point.

Tables for the adjusted isotopes, U-238, Pu-239 and U-235 are given in Appendix II. It has to be kept in mind that the fission spectra, which must be used in connection with the data of Appendixes I and II, are Maxwellion distributions with a temperature T = 1.35 MeV in the case of U-235 and T = 1.41 MeV (adjusted value, unadjusted T = 1.46 MeV) in the case of Pu-239.

4. - INTERFACES

As previously described /4/, the neutron cross section libraries in Bondarenko format are provided in a form suitable to be processed by neutronics calculation codes of general use, via the PRAVDA code /8/.

This capability was preserved with the ENDF/B-3 data (both adjusted and unadjusted). The list of the identification numbers for the isotopes, when used with the PRAVDA code, is given in Table II.

The data are also stored in the format required by the 1DX code /7/. This was done in view of a relevant improvement in the treatment of the elastic moderation, based on the continuous slowing-down theory /13/, which gave rise to a new version of the 1DX code /14/. Since the PRAVDA code did not include any special provision for this problem, which is one of the weak points of the self-shielding method, the 1DX code will probably be used in the future.

5. - CONCLUSIONS.

With the implementation of the ETOX code on the CNEN computer environment, it was possible to generate an up-to-date library for fast reactors calculations. This was the first step in the work in progress of optimal neutron cross sections generation, the next step being the adjustment of the multigroup parameters using a statistical procedure of correlation with integral experiments. Both adjusted and unadjusted cross sections for a large number of materials, were prepared in formats compatible with the interfaces with neutronics codes in use at CNEN. Future work in this field will be devoted to the already announced ENDF/B version 4 data. For what concerns the adjustment procedures, it is thought that in the future the correlation will be applied directly to the nuclear parameters and no more to the multigroup data. This is the so called consistent method /15/, which will give much more confidence to the adjusted data, which in turn will be in the form of a "corrected" data file to be processed by any of the existing multigroup cross section generation procedures.
