<sup>†††</sup>Centre de Spectrométrie Nucléaire et de Spectrométrie de Masse,  
 ORSAY, France

Our in-beam studies <sup>1)</sup> of the transitional odd-A Ir nuclei were extended to the reactions  $^{185}\text{Re}$  ( $\alpha$ , 4n)  $^{185}\text{Ir}$  and  $^{192}\text{Os}$  (d, 3n)  $^{191}\text{Ir}$ . In both nuclei a band built on 11/2-isomeric state (17ns and 4s in  $^{185}\text{Ir}$  and  $^{191}\text{Ir}$  respectively) was identified. If a triaxial shape is assumed for this band <sup>2)</sup> the relative level position (cf. fig.1) shows a continuous increase of the  $\gamma$  parameter when going from  $^{185}\text{Ir}$  to  $^{191}\text{Ir}$ . At present no information is available concerning the h 9/2 band in  $^{191}\text{Ir}$ . This band is however strongly fed in  $^{185}\text{Ir}$  and is well described by the Mottelson approximation (cf.ref.1) using only two adjustable parameters (see fig. 2).
