At LNS are available radioactive beams in an energy range from few MeV/A to 40 MeV/A. Low energy beams are provided by the EXCYT facility [1]; <sup>8</sup>Li was already produced with relatively good intensity, and also <sup>9</sup>Li is available. Intermediate energy beams are produced and selected using the in flight fragmentation method, with the FRIBS system [2]. Using these beams and the  $4\pi$  detector CHIMERA [3], we want to study excitation and decay of resonances in light exotic nuclei populated with transfer, pick-up and other reaction mechanisms. Measurements concerning <sup>10</sup>Li and <sup>11</sup>Be nuclei will be accomplished during 2009. Some preliminary results obtained with stable and unstable beams will be presented.
