Table of Contents

1 Introduction

This document describes the motivation, scope, requirements, and specification of the standard configuration and management protocol of an operational context which is capable of containing an OpenFlow 1.2 switch as described in (1). This configuration and management protocol is referred to as OF-CONFIG and is a companion protocol to OpenFlow. This document specifies version 1.0 of OF-CONFIG.

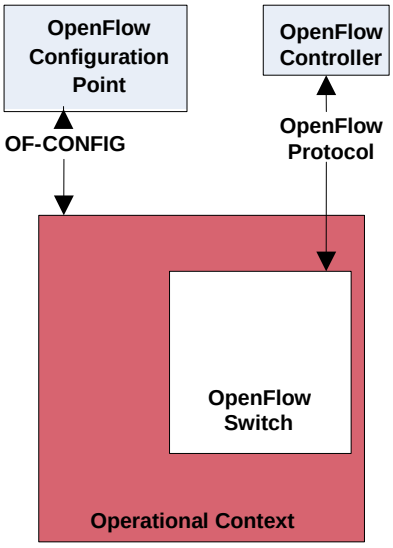

Figure 1: An OpenFlow Configuration Point communicates with an operational context which is capable of supporting an OpenFlow Switch using the OpenFlow Configuration and Management Protocol (OF-CONFIG)

The reader of this document is assumed to be familiar with the OpenFlow protocol and OpenFlow related concepts. Reading the OpenFlow whitepaper (2) and the OpenFlow Specification (1)is recommended prior to reading this document.

It is strongly recommended that switches which implement OF-CONFIG make changes to the OpenFlow operational context described in this document via OF-CONFIG and limit changes to the OpenFlow operational context via other methods (e.g. command line interfaces and other legacy management protocols). Future versions may better support other methods of change with detailed notification to the OpenFlow Configuration Point via OF-CONFIG.

2 Motivation

The OpenFlow protocol assumes that an OpenFlow datapath (e.g. an Ethernet switch which supports the OpenFlow protocol) has been configured with various artifacts such as the IP addresses of OpenFlow controllers. The motivation for the OpenFlow Configuration Protocol (OF-CONFIG) is to enable the remote configuration of OpenFlow datapaths. While the OpenFlow protocol generally operates on a time-scale of a flow (i.e. as flows are added and deleted), OF-CONFIG operates on a slower time-scale.

OF-CONFIG frames an OpenFlow datapath as an abstraction called an OpenFlow Logical Switch. The OF-CONFIG protocol enables configuration of essential artifacts of an OpenFlow Logical Switch so that an OpenFlow controller can communicate and control the OpenFlow Logical switch via the OpenFlow protocol.

OF-CONFIG 1.0 introduces an operating context for one or more OpenFlow datapaths called an OpenFlow Capable Switch. An OpenFlow Capable Switch is intended to be equivalent to a actual physical or virtual network element (e.g. an Ethernet switch) which is hosting one or more OpenFlow datapaths by partitioning a set of OpenFlow related resources such as ports and queues among the hosted OpenFlow datapaths. The OF-CONFIG protocol enables dynamic association of the OpenFlow related resources of an OpenFlow Capable Switch with specific OpenFlow Logical Switches which are being hosted on the OpenFlow Capable Switch. OF-CONFIG does not specify or report how the partitioning of resources on an OpenFlow Capable Switch is achieved. OF-CONFIG assumes that resources such as ports and queues are partitioned amongst multiple OpenFlow Logical Switches such that each OpenFlow Logical Switch can assume full control over the resources that is assigned to it.

OF-CONFIG 1.0 makes simplifying assumptions about the architecture of OpenFlow switches. The specification is deliberately decoupled from whether the switch supports flowvisor or other virtualization models.

The service which sends OF-CONFIG messages to an OpenFlow Capable Switch is called an OpenFlow Configuration Point. No assumptions are made about the nature of the OpenFlow Configuration Point. For example, it may be a service provided by software acting as an OpenFlow controller or it may by a service provided by a traditional network management framework. Any interaction between the OpenFlow Configuration Points and OpenFlow controllers is outside the scope of OF-CONFIG 1.0.

Figure 2 shows the basic abstractions detailed in OF-CONFIG 1.0 and the lines indicate that the OpenFlow Configuration Points and OpenFlow Capable Switches communicate via OF-OFCONFIG while OpenFlow Controllers and OpenFlow Logical Switches (i.e. datapaths) communicate via OpenFlow.

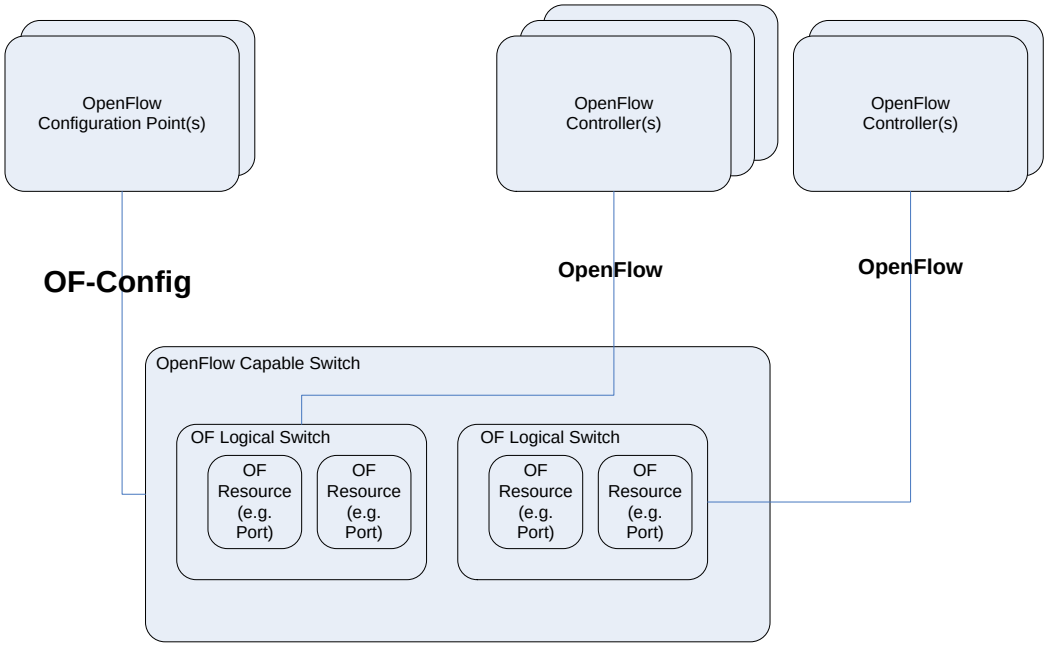

Figure 2 Relationship between components defined in this specification, the OF-CONFIG protocol and the OpenFlow protocol

A guiding principle in the development of this specification is to keep the protocol and schema simple and leverage existing protocols and schema models where possible. This helped in quick development of this specification and hopefully will also enable easier adoption, the motivation being to supplement the OpenFlow specification in a meaningful way to further drive the adoption of the software defined networking vision.

3 Scope

OF-CONFIG 1.0 is focused on the basic functions needed to configure an OpenFlow 1.2 (OFv1.2) datapath. Functionality to be configured includes:

- The assignment of one or more OpenFlow controllers
- The configuration of queues and ports
- The ability to remotely change some aspects of ports (e.g. up/down)

While limited in scope, OF-CONFIG1.0 lays the foundation on top of which various automated and more advanced configurations will be possible in future revisions. Tunnel configuration, switch discovery, topology discovery, capability reporting, event triggers, instantiation of OpenFlow Logical Switches, assignment of resources such as ports and queues to OpenFlow Logical Switches, and bootstrap of the OpenFlow capable network are outside the scope of OF-CONFIG 1.0 protocol. These may be included in future versions.

4 Normative Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 (3).

5 Terms

The following section lists several terms and definitions used in this document.

5.1 OpenFlow Capable Switch

An OpenFlow Capable switch is a physical or virtual switching device which can act an as operational context for an OpenFlow Logical Switch. OpenFlow Capable Switches contain and manage OpenFlow Resources which may be associated with an OpenFlow Logical Switch context.

5.2 OpenFlow Configuration Point

An OpenFlow Configuration Point configures one or more OpenFlow Capable Switches via the OpenFlow Configuration and Management Protocol (OF-CONFIG).

5.3 OpenFlow Logical Switch

An OpenFlow Logical Switch is a set of resources (e.g. ports) from an OpenFlow Capable Switch which can be associated with a specific OpenFlow Controller. An OpenFlow Logical switch is an instantiation of an OpenFlow Datapath as specified in (1).

5.4 OpenFlow Resource

An OpenFlow Resource is a resource (e.g. port or queue) which is associated with an OpenFlow Capable Switch and may be associated with an OpenFlow Logical Switch.

5.4.1 OpenFlow Queue

An OpenFlow Queue is a queuing resource of an OpenFlow Logical Switch as described in the OpenFlow specification as the queue component of an OpenFlow datapath.

5.4.2 OpenFlow Port

An OpenFlow Port is a forwarding interface of an OpenFlow Logical Switch as described in the OpenFlow specification as the port component of an OpenFlow datapath.

5.5 OpenFlow Controller

An OpenFlow Controller is software which controls OpenFlow Logical Switches via the OpenFlow protocol.

6 Requirements

This section describes requirements for the design of OF-CONFIG 1.0.

6.1 Requirements from the OpenFlow 1.2 Protocol Specification

The specification of version 1.2 of the OpenFlow protocol (1) includes explicit and implicit requirements for the configuration of OpenFlow switches. In (1) the term ‘configuration’ is used for two different kinds of operations: Configuration using the OpenFlow protocol and configuration outside of the OpenFlow protocol. The first kind of configuration is dealt with in (1). OF-CONFIG 1.0 enables other configuration of OpenFlow switches.

6.1.1 Connection Setup to a Controller

Section 6.2 (Connection Setup) of (1) discusses the process of setting up a connection between the OpenFlow switch and an OpenFlow controller. The switch initiates the connection applying three parameters that need to be configured in advance:

- the IP address of the controller
- the port number at the controller
- the transport protocol to use, either TLS or TCP

OF-CONFIG 1.0 must provide means for configuring these parameters.

6.1.2 Multiple Controllers

Section 6.3 of (1) discusses how a switch deals with multiple controllers simultaneously. This implicitly requires OF-CONFIG 1.0 to provide means for configuring multiple instances of the parameter set listed in 6.1.1 for specifying the connection setup to multiple controllers.

6.1.3 Openflow Logical Switches

The Openflow 1.2 protocol specifies various kinds of Openflow resources associated with an Openflow Logical Switch. The OF-CONFIG protocol must support the configuration of these Openflow resources associated with an Openflow Logical Switch. Examples of resources include queues and ports that have been assigned to an Openflow Logical Switch. It is assumed that Openflow Logical Switches have been instantiated out of band, for example, an administrator may have created them upfront. In addition, partitioning/assignment of Openflow resources amongst multiple Openflow switches that may exist in an Openflow Capable Switch has also been done out of band.

6.1.4 Connection Interruption

Section 6.4 of (1) discusses the choice of two modes the switch should immediately enter after losing contact with all controllers. The modes are

- fail secure mode
- fail standalone mode

OF-CONFIG protocol must provide means for configuring the mode to enter in such a case.

6.1.5 Encryption

Section 6.4 of (1) discusses encryption of connections to controllers that use TLS. It explicitly states “Each switch must be user-configurable with one certificate for authenticating the controller (controller certificate) and the other for authenticating to the controller (switch certificate)”. Hence, OF-CONFIG must provide means for configuring a switch certificate and a controller certificate for each controller that is configured to use TLS. This requirement is not addressed in OF-CONFIG 1.0 and will be addressed in a future version.

6.1.6 Queues

Section A.3.6 of (1) the configuration of queues. Queue in (1) have three parameters that may be configurable:

- min-rate
- max-rate
- experimenter

OF-CONFIG 1.0 must provide means for configuring these parameters.

6.1.7 Ports

The OpenFlow protocol already contains methods to configure ports of OpenFlow switches. The OpenFlow protocol specification (1) does not explicitly require an external configuration means, and therefore we cannot derive the. requirement for configuring ports from (1). However, the configuration of ports is an essential step of configuring a network and thus an obvious requirement for OF-CONFIG 1.0. Section A.2.1 of (1) defines the following parameters for port configuration:

- current-speed
- no-recv
- no-fwd
- no-packet-in
- link-down
- blocked
- live

OF-CONFIG 1.0 must provide means for configuring these parameters.

Also defined in the OpenFlow protocol specification are port features. There are four sets of these features for current, advertised, supported, and peer-advertised features. Feature sets

current, supported, and peer-advertised contain state information and are not to be configured. Only advertised features could potentially be configured with the following parameters:

- speed
- duplex-mode
- copper-medium
- fiber-medium
- auto-negotiation
- pause
- asymmetric-pause

OF-CONFIG 1.0 must provide means for configuring these advertised features.

6.1.8 Datapath ID

Section A.3.1 of (1) discusses the datapath ID of a switch. It is a 64-bit filed with the lower 48 bit intended for the switch MAC address and the remaining 16 bit left to the switch operator. Although not explicitly requested by (1), OF-CONFIG should provide means for configuring the datapath ID.

6.2 Operational Requirements

The OF-CONFIG 1.0 must meet support the following scenarios:

1. OF-CONFIG 1.0 must support an OpenFlow Capable Switch being configured by multiple OpenFlow Configuration Points.
2. OF-CONFIG 1.0 must support an OpenFlow Configuration Point managing multiple OpenFlow Capable Switches.
3. OF-CONFIG 1.0 must support an OpenFlow Logical Switch being controlled by multiple OpenFlow Controllers.
4. OF-CONFIG 1.0 must support configuring ports and queues of an OpenFlow Capable Switch that have been assigned to an OpenFlow Logical Switch.

6.3 Requirements for the Switch Management Protocol

OF-CONFIG 1.0 defines a communication standard between an OpenFlow switch and an OpenFlow Configuration Point. It consists of a network management protocol specified in Section 8 and a data model defined in Section 7. This subsection specifies requirements for the network management protocol. The protocol must comply with the following requirements:

1. The protocol must be secure providing integrity, privacy, and authentication. Authentication of both ends, switch and configuration point, must be supported.
2. The protocol must support reliable transport of configuration requests and replies.
3. The protocol must support connection setup by the configuration point.
4. The protocol should support connection setup by the switch.
5. The protocol must be able to carry partial switch configurations.
6. The protocol must be able to carry bulk switch configurations.
7. The protocol must support the configuration point setting configuration data at the switch

8. The protocol must support the configuration point retrieving configuration data from the switch.
9. The protocol should support the configuration point retrieving status information from the switch.
10. The protocol must support creation, modification and deletion of configuration information at the switch.
11. The protocol must support reporting on the result of a successful configuration request.
12. The protocol must support reporting error codes for partially or completely failed configuration requests.
13. The protocol should support sending configuration requests independent of the completion of previous requests.
14. The protocol should support transaction capabilities including rollback per operation.
15. The protocol must provide means for asynchronous notifications from the switch to the configuration point.
16. The protocol should be extensible.
17. The protocol should support reporting its capabilities.

7 Data Model

This section specifies the data model for OF-CONFIG 1.0. Configurations of an OpenFlow Capable Switch or for portions of it are encoded in XML. The data model is structured into classes and attributes of classes. Each class is described in a separate sub-section by

1. a UML diagram
   giving an overview of the class,
2. a portion of an XML schema
   extracted from the normative XML schema in Appendix A,
3. an example for XML code encoding an instance of the class,
4. normative constraints for instances of the class
   extending the XML schema by semantic specifications,
5. a portion of a YANG (9) module
   extracted from the YANG module in Appendix B.

The full XML schema and the full YANG module are listed in Appendices A and B. Normative for OF-CONFIG 1.0 is the XML schema in Appendix A and the normative constraints in sub-sections 7.X.4. The YANG module in Appendix B incorporates the XML schema specifications as well as the normative constraints.

OF-CONFIG specific terminology used for describing the model is defined in Section 5. The following UML diagram describes the top-level classes of the data model.

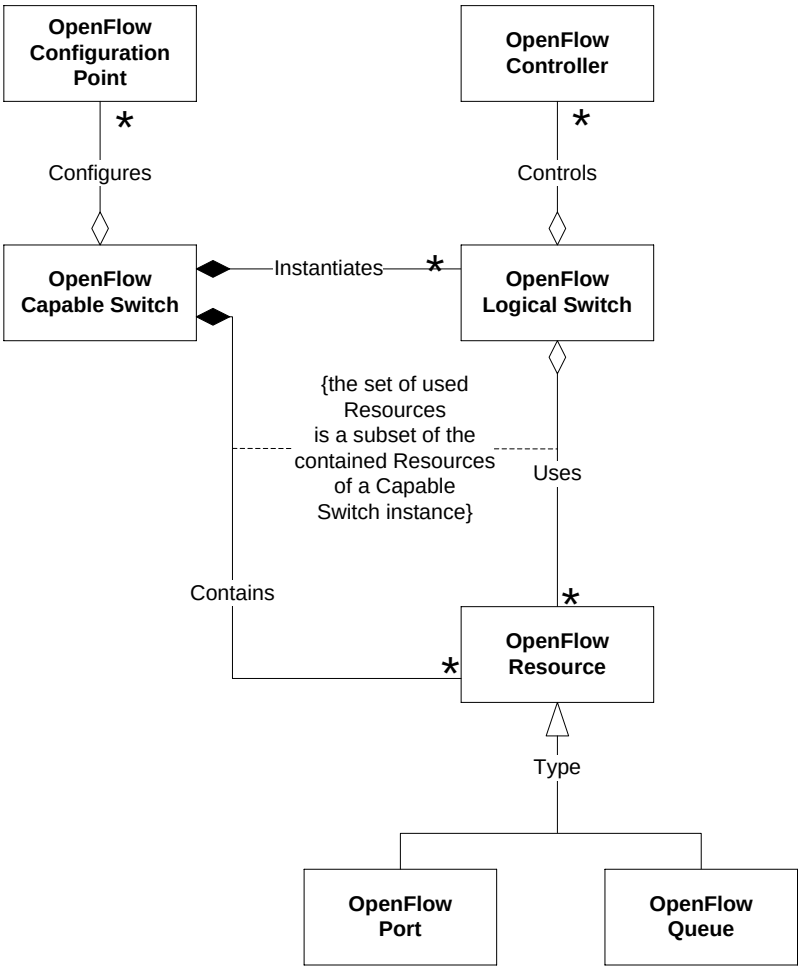

Figure 3: UML Class Diagram for OF-CONFIG Data Model

The core of the model is an OpenFlow Capable Switch that is configured by OpenFlow Configuration Points.

The switch contains a set of resources of different types. For OF-CONFIG 1.0, two types of resources are included in the model: OpenFlow Ports and OpenFlow Queues. More resource types may be added in future revisions of OF-CONFIG. OpenFlow resources can be made available for use to OpenFlow Logical Switches.

Instances of OpenFlow logical switches are contained within the OpenFlow Capable Switch. A set of OpenFlow Controllers is assigned to each OpenFlow logical switch.

The data model contains several identifiers, most of them encoded as an XML element `<id>`. Currently these IDs are defined as strings with required uniqueness in a certain context. Beyond uniqueness requirements, no further guidance is given on how to build these strings. This may be changed in the future. Particularly, the use of Universal Resource Names (URNs) is envisioned. This requires developing a naming scheme for URNs in OF-CONFIG and registering a URN namespace for the ONF. It is expected that recommendations for URN-based

identifiers will be introduced by a future version of OF-CONFIG. Since URNs are represented as strings, such recommendations can be made compatible with identifiers in OF-CONFIG v1.0.

When issuing a NETCONF `get` request all elements in the requested sub-tree must be returned in the result. Those elements that can be modified by a NETCONF `edit-config` request or retrieved by a NETCONF `get-config` request are identified in the normative constraints sub-sections 8.X.4.

7.1 OpenFlow Capable Switch

The OpenFlow Capable Switch serves as the root element for an OpenFlow configuration. It has relationships to

- OpenFlow Configuration Points that manage and particularly configure the OpenFlow Capable Switch,
- OpenFlow logical switches that are contained and instantiated within the OpenFlow Capable Switch,
- OpenFlow Resources contained in the OpenFlow Capable Switch that may be used by OpenFlow Logical Switches.

7.1.1 UML Diagram

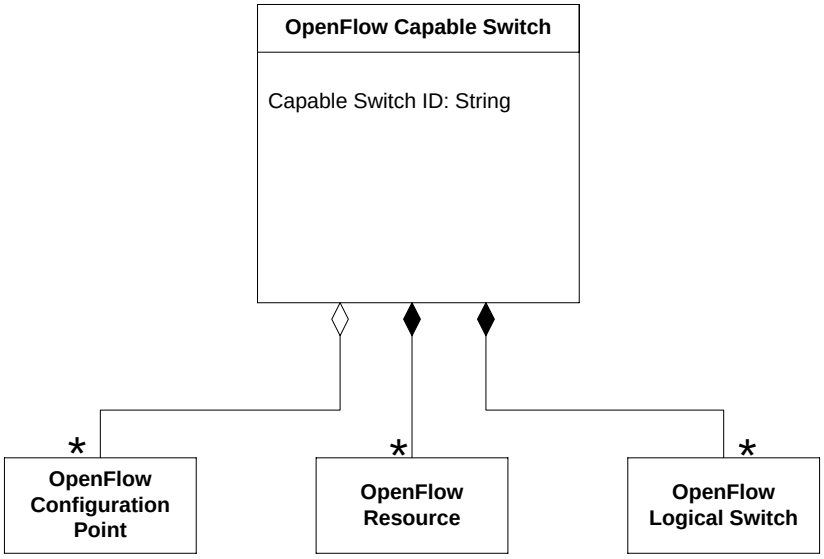

Figure 4: Data Model Diagram for OpenFlow Capable Switch

7.1.2 XML Schema

```
<xs:complexType name="OFCapableSwitchType">
  <xs:sequence>
    <xs:element name="id"
                type="OFConfigID"/>
    <xs:element name="configuration-points"
         type="OFConfigurationPointListType"/>
    <xs:element name="resources"
         type="OFCapableSwitchResourceListType"/>
    <xs:element name="logical-switches"
         type="OFLogicalSwitchListType"/>
  </xs:sequence>
</xs:complexType>

<xs:complexType name="OFConfigurationPointListType">
  <xs:sequence>
    <xs:element name="configuration-point"
                type="OFConfigurationPointType"
                maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>

<xs:complexType name="OFCapableSwitchResourceListType">
  <xs:sequence>
    <xs:element name="port"
                type="OFPortType" maxOccurs="unbounded"/>
    <xs:element name="queue"
                type="OFQueueType" maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>

<xs:complexType name="OFLogicalSwitchListType">
  <xs:sequence>
    <xs:element name="logical-switch"
                type="OFLogicalSwitchType"
                maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>
```

7.1.3 XML Example

```
<capable-switch>
  <id>CapableSwitch0</id>
  <configuration-points>
    ...
  </configuration-points>
  <resources>
    ...
  </resources>
  <logical-switches>
    ...
  </logical-switches>
</capable-switch>
```

7.1.4 Normative Constraints

The OpenFlow Capable Switch is identified by the OpenFlow Configuration Point with identifier `<id>`. The identifier MUST be unique within the context of potential OpenFlow Configuration Points. It MUST be persistent across reboots of the OpenFlow Capable Switch.

Element `<configuration-points>` contains a list of all Configuration Points known to the OpenFlow Capable Switch that manage it or have managed it using OF-CONFIG.

Element `<resources>` contains lists of all resources of an OpenFlow Capable Switch that can be used by OpenFlow Logical Switches. Resources are listed here independent of their actual assignment to OpenFlow Logical Switches. They may be available to be assigned to an OpenFlow Logical Switch or already in use by an OpenFlow Logical Switch.

Element `<logical-switches>` contains a list of all OpenFlow Logical Switches available on the OpenFlow Capable Switch.

7.1.5 YANG Specification

```
container capable-switch {
   description "The OpenFlow Capable Switch containing logical switches,
     and resources that can be assigned to logical switches.";
   leaf id {
   type inet:uri;
     mandatory true;
     description "An unique but locally arbitrary identifier that
       identifies a Capable Switch towards the management system and
       is persistent across reboots of the system.";
   }
   container configuration-points {
     list configuration-point {
       key "id";
       unique "id";
       description "The list of all Configuration Points known to the
         OpenFlow Capable Switch that may configure it using OF-
         CONFIG.";
       uses openflow-configuration-point-grouping;
     }
   }
   container resources {
     description "A lists containing all resources of the OpenFlow
       Capable Switch.";
...
   }
   container logical-switches {
     description "This element contains all OpenFlow Logical Switches
       on the OpenFlow Capable Switch.";
     list switch {
       key "id";
       unique "id";
       description "The list of all OpenFlow Logical Switches the
         OpenFlow Capable Switch.";
       uses openflow-logical-switch-grouping;
     }
   }
}
```

7.2 OpenFlow Configuration Point

The Configuration Point is an entity that manages the switch using the OF-CONFIG protocol. Attributes of an OpenFlow Configuration Point allow the OpenFlow Capable Switches to identify a Configuration Point and specify which protocol is used for communication between Configuration Point and OpenFlow Capable Switch. The OpenFlow Capable Switch stores a list of Configuration Points that manage it or have managed it. An OpenFlow Configuration Point is to an OpenFlow Capable Switch what an OpenFlow Controller is to an OpenFlow Logical switch.

Instances of the Configuration Point class are used by switches to connect to a configuration point. Currently the only transport mapping that supports a connection set-up initiated by the switch to be configured is the mapping to the BEEP protocol (5). Other NETCONF transport

mappings (6,7,8) may be extended in the future to also support connection set-up in this direction.

7.2.1 UML Diagram

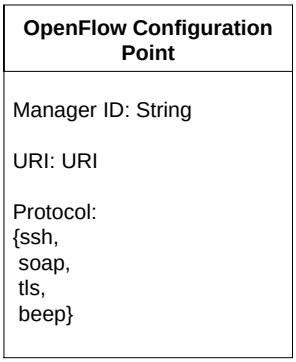

Figure 5: Data Model Diagram for an OpenFlow Configuration Point

7.2.2 XML Schema

```
<xs:complexType name="OFConfigurationPointType">
  <xs:sequence>
    <xs:element name="id"
                type="OFConfigID"/>
    <xs:element name="uri"
                type="inet:uri"/>
    <xs:element name="protocol"
                type="OFConfigurationPointProtocolType"/>
  </xs:sequence>
</xs:complexType>

<xs:simpleType name="OFConfigurationPointProtocolType">
  <xs:restriction base="xs:string">
    <xs:enumeration value="ssh"/>
    <xs:enumeration value="soap"/>
    <xs:enumeration value="tls"/>
    <xs:enumeration value="beep"/>
  </xs:restriction>
</xs:simpleType>
```

7.2.3 XML Example

```
<configuration-point>
  <id>ConfigurationPoint1</id>
  <uri>uri0</uri>
  <protocol>ssh</protocol>
<configuration-point>
```

7.2.4 Normative Constraints

OF-CONFIG uses the NETCONF protocol as described in Section 8. NETCONF can use four different transport protocols: SSH, BEEP, SOAP, and TLS. Element `<protocol>` defines the transport protocol that the Configuration Point used last when communicating via NETCONF with the OpenFlow Capable Switch. If this element is missing, then the default protocol is SSH.

When an OpenFlow Capable Switch connects to a configuration point it must make sure that the used connection information is stored in an instance of the Configuration Point class. If such an instance does not exist, the OpenFlow Capable Switch MUST create an instance that it fills with connection information.

An OpenFlow Capable Switch that cannot initiate a connection to a configuration point does not have to implement the Configuration Point class. It SHOULD block attempts to write to instances of the Configuration Point class with NETCONF <edit-config>operations.

Instances of the Configuration Point class SHOULD be stored persistently across reboots of the OpenFlow Capable Switch.

A Configuration Point is identified by OpenFlow Capable Switches with identifier `<id>`. The identifier MUST be unique within the context of potential OpenFlow Capable Switches.

Element `<uri>` identifies the location of the configuration point as a service resource and MUST include all information necessary for the OpenFlow Capable Switch to reconnect to the Configuration Point should it become disconnected (e.g. protocol, fully qualified domain name, and port).

The following elements of the Configuration Point can be modified by a NETCONF `edit-config` request or retrieved by a NETCONF `get-config` request: `<id>, <uri>, <protocol>`.

7.2.5 YANG Specification

```
grouping openflow-configuration-point-grouping {
description "Representation of an OpenFlow Configuration Point.";
   leaf id {
     type inet:uri;
     description "An identifier that identifies a Configuration Point
       of the OpenFlow Capable Switch.";
   }
   leaf uri {
     type inet:uri;
     description "A locator of the Configuration Point. This element
       MAY contain a locator of the Configuration Point including, for
       example, an IP address and a port number.";
   }
   leaf protocol {
     type enumeration {
       enum "ssh";
       enum "soap";
       enum "tls";
       enum "beep";
     }
     default "ssh";
     description "The transport protocol that the Configuration Point
       uses when communicating via NETCONF with the OpenFlow Capable
       Switch.";
     reference "The mappings of NETCONF to different transport
       protocols are defined in RFC 6242 for SSH, RFC 4743 for SOAP,
       RFC 4744 for BEEP, and RFC 5539 for TLS";
```

```
    }
}
```

7.3 OpenFlow Logical Switch

The OpenFlow Logical Switch represents an instant of a logical switch that is available or can be made available on an OpenFlow Capable Switch. An OpenFlow Logical switch is a logical context which behaves as the datapath as described in the OpenFlow specification. The OpenFlow Logical Switch is connected to one or more OpenFlow Controllers via the OpenFlow protocol. It uses resources of the OpenFlow Capable Switch for realizing the capabilities offered via the OpenFlow protocol. The OpenFlow Logical Switch has relationships to

- OpenFlow Controllers that control the OpenFlow Capable Switch
- OpenFlow Resources that are available from the OpenFlow Capable Switch

7.3.1 UML Diagram

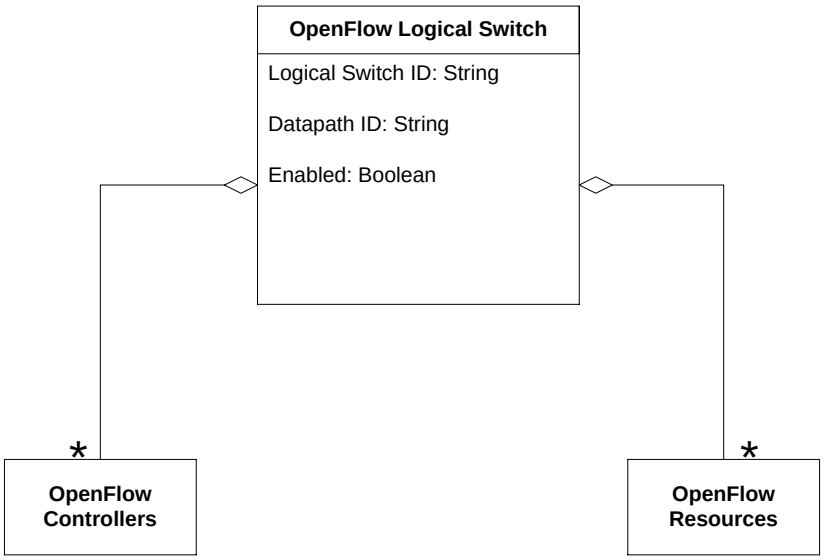

Figure 6: Data Model Diagram for an OpenFlow Logical Switch

7.3.2 XML Schema

```
<xs:complexType name="OFLogicalSwitchType">
  <xs:sequence>
    <xs:element name="id"
                type="OFConfigID"/>
    <xs:element name="datapath-id"
                type="OFConfigID"/>
    <xs:element name="enabled"
         type="xs:boolean"/>
    <xs:element name="lost-connection-behavior"
                type="OFLogicalSwitchLostConnnectionBehavior"/>
    <xs:element name="controllers"
                type="OFControllerListType"/>
    <xs:element name="resources"
                type="OFLogicalSwitchResourceListType"/>
  </xs:sequence>
```

```
</xs:complexType>

<xs:simpleType name="OFLogicalSwitchLostConnnectionBehavior">
  <xs:restriction base="xs:string">
    <xs:enumeration value="failSecureMode"/>
    <xs:enumeration value="failStandaloneMode"/>
  </xs:restriction>
</xs:simpleType>

<xs:complexType name="OFControllerListType">
  <xs:sequence>
    <xs:element name="controller"
                type="OFControllerType"
                maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>

<xs:complexType name="OFLogicalSwitchResourceListType">
  <xs:sequence>
    <xs:element name="port"
                type="OFConfigID" maxOccurs="unbounded"/>
    <xs:element name="queue"
                type="OFConfigID"
                maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>
```

7.3.3 XML Example

```
<logical-switch>
  <id>LogicalSwitch5</id>
  <datapath-id>datapath-id0</datapath-id>
  <enabled>true</enabled>
  <lost-connection-behavior>failSecureMode</lost-connection-behavior>
  <controllers>
    ...
  </controllers>
  <resources>
    <port>port2</port>
    <port>port3</port>
    <queue>queue0</queue>
    <queue>queue1</queue>
  </resources>
</logical-switch>
```

7.3.4 Normative Constraints

An OpenFlow Logical Switch is identified by identifier `<id>`. The identifier MUST be unique within the context of the OpenFlow Capable Switch. It MUST be persistent across reboots of the OpenFlow Capable Switch.

Element `<datapath-id>` identifies the OpenFlow Logical Switch to the OpenFlow controllers that has been assigned to the OpenFlow Logical Switch. The `<datapath-id>` MUST be unique within the context of OpenFlow Controllers associated with OpenFlow Logical

Switch.The <datapath-id>is a string value that MUST be formatted as a sequence of 10 2-digit hexadecimal numbers that are separated by colons, e.g.,01:23:45:67:89:ab:cd:ef:01:23. The case of the hexadecimal digits MUST be ignored.

Element <enabled> denotes the administrative state of the OpenFlow Logical Switch. A value of false means the OpenFlow Logical Switch MUST NOT communicate with any OpenFlow Controllers, MUST NOT conduct any OpenFlow processing, and SHOULD NOT be utilizing computational or network resources of the underlying platform.

Element <lost-connection-behavior> defines the behavior of the OpenFlow Logical Switch in case it looses contact with all controllers. Section 6.4 of the OpenFlow specification 1.2 defines two alterantive modes in such a case: fails secure mode and fail standalone mode. These are the only llowed values for this element. Default is the fail secure mode.

Element <resources> contains the list of all resources of the OpenFlow Capable Switch that the OpenFlow Logical Switch has exclusive access to. Any resource identified in the <resources>list of a Logical Switch MUST be present in the <resources> list of the OpenFlow Capable Switch containing the OpenFlow Logical Switch. Any resource identified in the <resources> list of anOpenFlow Logical Switch MUST NOT be identified in the <resources> list of any other OpenFlow Logical Switch.

The following elements of the OpenFlow Logical Switch can bemodified by a NETCONF edit-config request or retrieved by a NETCONF get-config request: <id>, <datapath-id>, <enabled>. Elements in the <resources> list can also be modified and retrieved by those commands.

7.3.5 YANG Specification

```
typedef datapath-id-type {
   type string {
     pattern
       '[0-9a-fA-F]{2}(:[0-9a-fA-F]{2}){7}';
   }
   description "The datapath-id type represents an OpenFlow datapath
     identifier.";
}

grouping openflow-logical-switch-grouping {
   description "This grouping specifies all properties of an OpenFlow
     Logical Switch.";
   leaf id {
     type inet:uri;

```

7.4 OpenFlow Controller

The OpenFlow Controller class represents an entity that acts as OpenFlow Controller of an OpenFlow Logical Switch. Attributes of the class indicate the role of the controller and parameters of the OpenFlow connection to the controller.

7.4.1 UML Diagram

       <version>1.1</version>
     </supported-versions>
   </state>
</controller>
```

7.4.4 Normative Constraints

An OpenFlow Controller is identified by identifier `<id>`. The identifier MUST be unique within the context of the OpenFlow Capable Switch. It MUST be persistent across reboots of the OpenFlow Capable Switch.

Element `<role>` indicates the role of the controller. Semantics of these roles are specified in the OpenFlow 1.2 specification. It is RECOMMENDED that the roles of controllers are not configured by OF-CONFIG 1.0 but determined using the OpenFlow 1.2 protocol. Controllers configured by OF-CONFIG 1.0 SHOULD have the default role “equal”. A role other than “equal” MAY be assigned to a controller. Roles “slave” and “equal” MAY be assigned to multiple controllers. Role “master” MUST NOT be assigned to more than one controller.

Elements `<ip-address>` and `<port>` indicate the IP address and the port number of the OpenFlow Controller. The port number is optional. If not present, the default port number 6633 is assumed to be used.

Elements `<local-ip-address>` and `<local-port>` indicate the IP address and the port number used by the OpenFlow Logical Switch. Both elements are optional.

Element <protocol> indicates the transport protocol used for the OpenFlow connection. OpenFlow supports two transport protocols, TCP and TLS. If this optional element is not present, TLS is assumed to be used.

Element <state> represents various elements of known state of the OpenFlow Controller. Element <connection-state>represents the administrative state of the OpenFlow connection between the OpenFlow Logical Switch and the OpenFlow Controller. A value of down means that the OpenFlow Logical Switch MUST NOT communicate with the OpenFlow Controller via theOpenFlow protocol. If the value of <connection-state> is set to up, element <current-version>MUST represent the version of the OpenFlow protocol in use between the OpenFlow Logical Switch and the OpenFlow Controller. The element <supported-versions>represents the versions of the OpenFlow protocol that the OpenFlow Controller supports.<supported-versions> SHOULD be set to all versions of the OpenFlow protocol supported by the OpenFlow Controller.

The following elements of the OpenFlow Controller can be modified by a NETCONF edit-config request or retrieved by a NETCONF get-config request: <id>, <role>, <ip-address>, <port>, <local-ip-address>, <local-port>, <protocol>, <connection-state>, <current-version>, <supported-versions>.

7.4.5 YANG Specification

```
typedef openflow-version {
   type enumeration {
     enum "1.0";
     enum "1.1";
     enum "1.2";
   }
   description "This enumeration contains the all OpenFlow versions
     released so far.";
}

grouping openflow-controller-grouping {
   description "This grouping specifies all properties of an OpenFlow
     Logical Switch Controller.";
   leaf id {

      type inet:ip-address;
      description "This specifies the source IP for packets sent to
        this controller and overrides the default IP used.";
    }
    leaf local-port {
      type inet:port-number;
      default 0;
      description "The port number the switch listens on. If 0 the port
        is chosen dynamically.";
    }
    leaf protocol {
      type enumeration {
        enum "tcp";
        enum "tls";
      }
      default "tcp";
      description "The protocol used for connecting to the
        controller.";
      }
    container state {
      description "This container holds connection state information
        that indicate if the Logical Switch is connected, what versions
        are supported, and which one is used.";
      leaf connection-state {
        type up-down-state-type;
        description "This object indicates if the Logical Switch is
          connected to the controller.";
      }
      leaf current-version {
        type openflow-version;
        description "This object contains the current OpenFlow version
          used between Logical Switch and Controller.";
      }
      leaf-list supported-versions {
        type openflow-version;
        description "This list of objects contains all the OpenFlow
          versions supported the controller.";
      }
    }
}
```

7.5 OpenFlow Resource

OpenFlow Resource is a superclass of OpenFlow Port and OpenFlow Queue. The superclass contains the identifier attribute that is inherited by all subclasses in addition to their individual identifiers.

7.5.1 UML Diagram

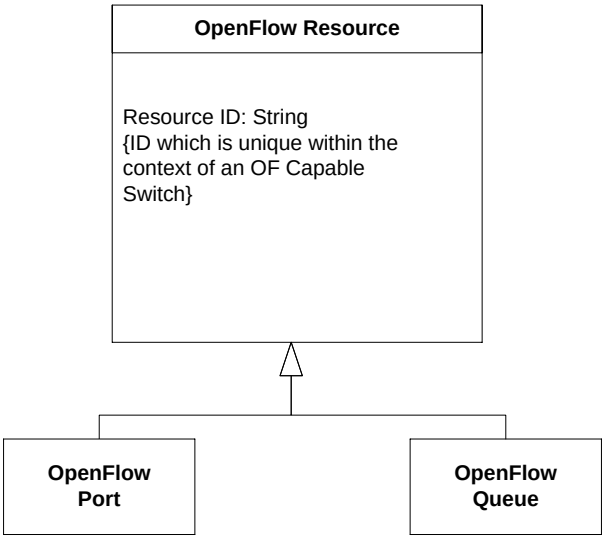

Figure 8: Data Model Diagram for an OpenFlow Resource

7.5.2 XML Schema

```
<xs:complexType name="OFResourceType">
  <xs:sequence>
    <xs:element name="resource-id" type="OFConfigID"/>
  </xs:sequence>
</xs:complexType>
```

7.5.3 XML Example

The superclass is not instantiated.

7.5.4 Normative Constraints

An OpenFlow Resource is identified by identifier `<resource-id>`. The identifier MUST be unique within the context of the OpenFlow Capable Switch. It MUST be persistent across reboots of the OpenFlow Capable Switch.

7.5.5 YANG Specification

The base OpenFlow Resource has no specific correspondence in the YANG specification. The <resource-id> property is included in each individual resource.

7.6 OpenFlow Port

The OpenFlow Port is an instance of an OpenFlow resource. It contains a port configuration object, a port state object and a list of port feature objects. While there can't be more than one instance of the port configuration and the port state, there may be multiple Port Features. The

OpenFlow Port is a logical context which represents a port as described in the OpenFlow protocol specification.

7.6.1 UML Diagram

    <supported>
      ...
    </supported>
    <advertised-peer>
      ...
    </advertised-peer>
  </features>
</port>
```

7.6.4 Normative Constraints

An OpenFlow Port is identified by identifier `<resource-id>`within the context of the OpenFlow Capable Switch and OpenFlow Logical Switches. Element`<resource-id> is` inherited from superclass OpenFlow Resource.

Element `<number>`identifies the OpenFlow Port to OpenFlow Controllers. If the OpenFlow Port is associated with a OpenFlow Logical Switch, `<number>`MUST be unique within the context of the OpenFlow Logical Switch.

Element `<name>` assists OpenFlow Controllers in identifying OpenFlow Ports. `<name>` MAY be defined. If the OpenFlow Port is associated with a OpenFlow Logical switch and `<name>` is defined, `<name>`MUST be unique within the context of the OpenFlow Logical Switch.

Elements `<current-rate>` and `<max-rate>` indicate the current and maximum bit rate of the port. Both values are to be provided in units of kilobit per second (kbps). Those elements are only valid if the element `<rate>` in the current Port Features has a value of `other`.

Element `<configuration>`represents the expected behavior of the port based on explicit configuration.

Element `<configuration>` contains four further elements: `<admin-state>`, `<no-receive>`, `<no-forward>`, `<no-packet-in>`.

Element `<admin-state>` represents the configured link state of the port and MUST be set to either `up` or `down`.

Element `<no-receive>` MUST be set to either `true` or `false`. A value of `true` means the port is not receiving any traffic.

Element <no-forward>MUST be set to either true or false. A value of true means the port is not forwarding any packets.

Element <no-packet-in> MUST be set to either true or false. A value of true means port is not receiving any packets.

Element <state> contains three further elements: <oper-state>, <blocked>, <live>.

Element <oper-state> represents the reported link state of the port and MUST have a value of either up or down.

Element <blocked> MUST have a value of either true or false. A value of true meansthe port has been blocked from receiving or sending traffic.

Element <live> MUST have a value of either true or false .A value of true means the portis active and sending/receiving packets.

An OpenFlow Port contains a list of OpenFlow Port Features in element <features>which contains four sub-lists represented by elements <current>, <advertised>, <supported>,<advertised-peer>.These four lists MUST contain the features associated with the OpenFlow Port. The specific semantics of feature membership in each of these four sub-lists are defined in the OpenFlow protocol.

The following elements of the OpenFlow Port can bemodified by a NETCONF edit-config request or retrieved by a NETCONF get-config request: <resource-id>, <number>, <name>, <admin-state>, <no-receive>, <no-forward>, <no-packet-in>.

7.6.5 YANG Specification

<medium>copper</medium>
<pause>symmetric</pause>
```

7.7.4 Normative Constraints

The OpenFlow Port has several attributes configurable via OF-CONFIG protocol. The normative semantics of these attributes are described in the OpenFlow protocol.

Element `<rate>`MUST indicate a valid forwarding rate. The current Port Feature set MUST contain this element exactly once. The other Port Feature sets MAY contain this element more than once. If this element appears more than once in a Port Feature set than the value MUST be unique within the Port Feature set.

Element `<auto-negotiate>`MUST indicate an administrative state of the forwarding rate auto-negotiation protocol.

Element `<medium>`MUST indicate a valid physical medium. The current Port Feature set MUST contain this element exactly once. The other Port Feature sets MAY contain this element more than once. If this element appears more than once in a Port Feature set than the value MUST be unique within the Port Feature set.

Element `<pause>`MUST indicate the flavor of the pause function by indicating either `asymmetric` or `asymmetric`.

The following elements in the advertised Port Feature set can bemodified by a NETCONF `edit-config` request or retrieved by a NETCONF `get-config` request: `<rate>`, `<auto-negotiate>`, `<medium>`, `<pause>`.

7.7.5 YANG Specification

```

```

7.8 OpenFlow Queue

The OpenFlow Queue is an instance of an OpenFlow resource. It contains list of queue properties. The OpenFlow Queue is a logical context which represents a queue as described in the OpenFlow protocol specification.

7.8.1 UML Diagram

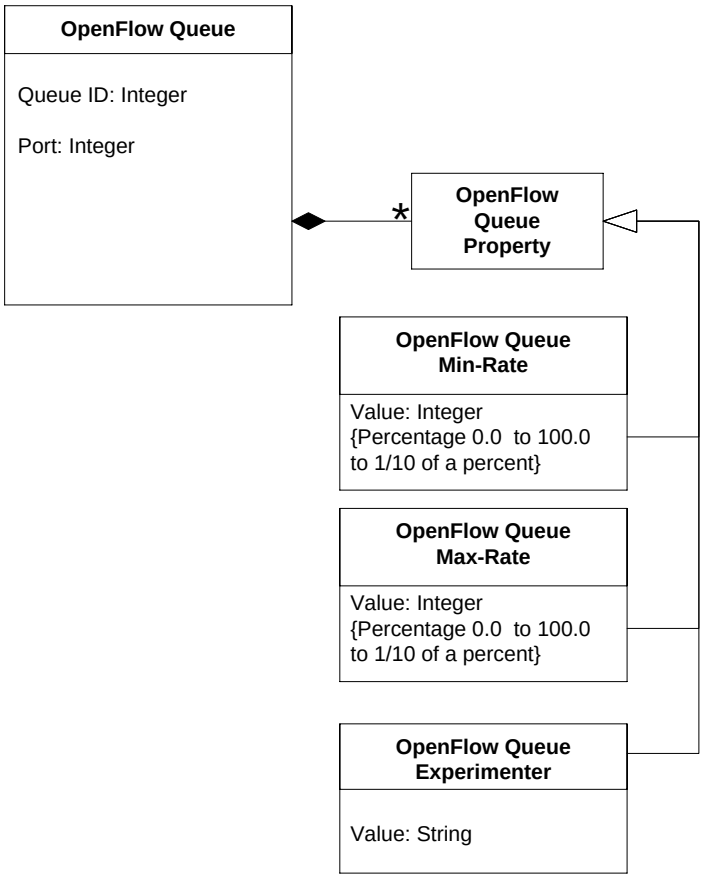

Figure 11: Data Model Diagram for an OpenFlow Queue

7.8.2 XML Schema

```
<xs:complexType name="OFQueueType">
  <xs:complexContent>
    <xs:extension base="OFResourceType">

</xs:simpleType>
```

7.8.3 XML Example

```
<queue>
  <resource-id>Queue2</resource-id>
  <id>2</id>
  <port>4</port>
  <properties>
    <min-rate>10</min-rate>
    <max-rate>500</max-rate>
    <experimenter>123498</experimenter>
    <experimenter>708</experimenter>
  </properties>
</queue>
```

7.8.4 Normative Constraints

An OpenFlow Queue is identified by identifier `<resource-id>`within the context of the OpenFlow Capable Switch and OpenFlow Logical Switches. Element `<resource-id> is` inherited from superclass OpenFlow Resource.

Element `<id>` identifies the OpenFlow Queue to OpenFlow Controllers. If the OpenFlow Queue is associated with a OpenFlow Logical Switch, `<id>`MUST be unique within the context of the OpenFlow Logical Switch.

Element `<port>` associates an OpenFlow Queue with an OpenFlow Port. If the OpenFlow Queue is associated with an OpenFlow Logical Switch*S* and `<port>` is non-empty, `<port>` MUSTbe set to the value of the `<resource-id>` of an OpenFlow Port which is associated with the OpenFlow Logical Switch *S*.

Element `<properties>` indicates the properties associated with the OpenFlow Queue as defined in the OpenFlow protocol specification. If the OpenFlow Queue is associated with an OpenFlow Logical Switch, `<properties>`MUST include the properties associated to the OpenFlow Queue. Element `<properties>` contains three possible elements: `<min-rate>`, `<max-rate>`, `<experimenter>`.

Element <min-rate>MUST indicate the minimum rate of the queue by percentage as an integer representing one tenth of one percent.

Element <max-rate> MUST indicate the minimum rate of the queue by percentage as an integer representing one tenth of one percent.

Element <experimenter>MAY indicate values as defined in the OpenFlow protocol specification.

The following elements of the OpenFlow Port can bemodified by a NETCONF edit-config request or retrieved by a NETCONF get-config request: <resource-id>, <id>, <port>, <min-rate>, <max-rate>, <experimenter>.

7.8.5 YANG Specification

```
typedef tenth-of-a-percent {
    type uint16 {
      range "0..1000";
    }
    units "1/10 of a percent";
    description "This type defines a value in tenth of a percent.";
}

grouping openflow-queue-resource-grouping {
   description "This grouping specifies all properties of a queue
     resource.";
   leaf resource-id {

        properties used.";
    }
  }
}
```

8 Binding to NETCONF

The OF-CONFIG1.0 protocol provides a standard way to modify basic OpenFlow configuration for the operation of an OpenFlow logical switch within the context of an OpenFlow Capable Switch. At the same time, it provides vendors the ability to extend and innovate by providing new and imporved configuration capabilities. To achieve these goals, OF-CONFIG1.0 requires that devices supporting OF-CONFIG1.0 MUST implement NETCONF protocol (4) as the transport. This in turn implies as specified by NETCONF specification that OpenFlow Capable Switches supporting OF-CONFIG1.0 must implement SSH as a transport protocol. In addition, the OpenFlow Capable Switches implementing OF-CONFIG1.0 protocol may implement additional transports such as Web Services-Management or something else. Future versions of OF-CONFIG may specify binding to these additional transports.

NETCONF is a stable protocol that has been standardized for several years now. It is widely available on various platforms and achieves the needs for OF-CONFIG1.0. NETCONF defines a set of operations on top of a messaging layer (RPC). Below diagram shows the various layers of NETCONF protocol.

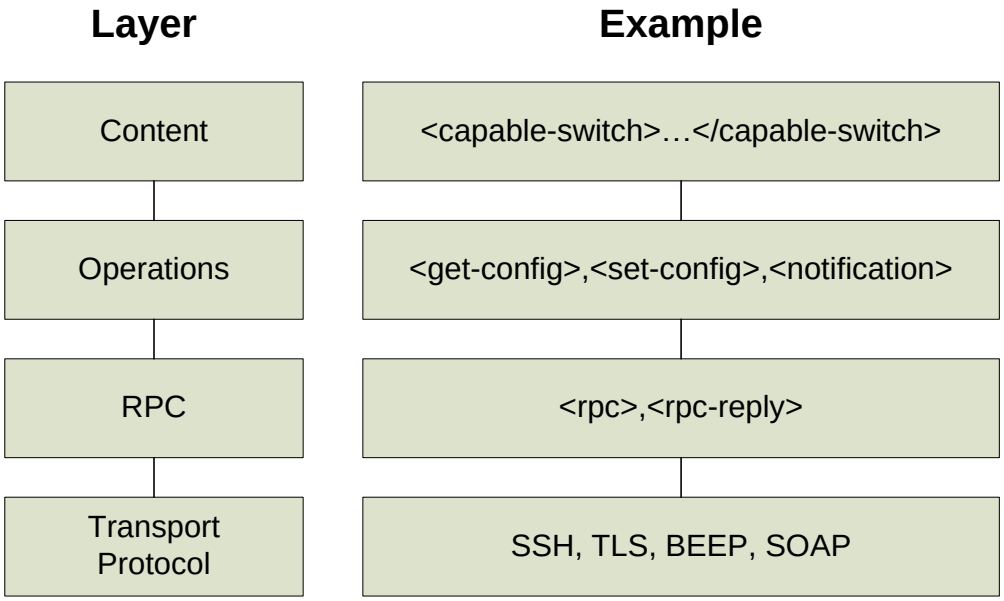

Figure 12 NETCONF Layers and Examples

The OpenFlow capable switches MUST support the schema as defined in this specification as the content layer in the above diagram. The schema currently covers basic configuration elements and will be extended in next versions.

The NETCONF protocol meets the OF-CONFIG 1.0 requirements for communication between an OpenFlow Configuration Point and an OpenFlow switch as listed in Section 6.3. In addition, if

future needs of OF-CONFIG are not met by NETCONF protocol, NETCONF is extensible which will allow OF-CONFIG to extend NETCONF for its purpose.

1. It supports TLS as communication transport protocol (directly or with SOAP or BEEP in between) that can be used for providing integrity, privacy, and mutual authentication.
2. All specified transport mappings for NETCONF use TLS or TCP as underlying transport protocol and thus provides reliable transport.
3. The common way to establish a connection with NETCONF is from the Configuration Point (configuration point) to the managed device (switch).
4. The NETCONF standard support reversed configuration setup only if BEEP is used as transport protocol.
5. I supports partial switch configuration to the most fine-grain level.
6. It supports full switch configuration with a single operation.
7. It supports setting of configuration data.
8. It supports the retrieval of configuration data.
9. It support the retrieval of (non-configuration) status data.
10. It supports creation, modification and deletion of configuration information.
11. It supports returning success codes after completing a configuration operation.
12. It supports support reporting error codes for partially or completely failed configuration requests.
13. It supports sending configuration requests independent of the completion of previous requests. Requests may be queued or processed concurrently at a switch. Each request has a request ID. Success or failure indications can be send independently of other requests individually for each request ID.
14. It supports transaction capabilities including rollback per operation.
15. With its extension defined in RFC 5277 it supports asynchronous notifications from the managed device (switch) to the Configuration Point (configuration point).
16. It is extensible. New operations can bee added and its support can be checked by capability retrieval.
17. It supports reporting its capabilities.

12 Appendix C: Revision History

Version	Date	Notes
0.0.1	10/4/11	Initial outline and conversation starter
1.2v4R1	10/6/11	Revisions based on 10/6 phone conference
1.2v5R1	10/19/11	Revisions based on mailing-list conversations
1.2V5R2	10/24/11	Revisions based on face-to-face meeting on 10/20/11
1.2V5R3	11/2/11	Revisions based on 10/31 meeting
1.2V6R1	11/3/11	Revisions based on 11/3 meeting, and merges 1.2V4R4-Deepak
1.2V7R1	11/6/11	Revisions based on 11/3 meeting and implementation experience
1.2V7R3	11/7/11	Revisions based on 11/7 call
1.2.V8R1	11/9/11	Accepted changes from V7R4
1.2.V8R3	11/13/11	Added class descriptions and normative constraints to data model
1.2V8R4	11/13/11	Removed all references to Meters, added OpenFlow-State class to Controller, updated Queues to be consistent with 1.2
1.2V10R1	11/14/11	Feature complete UML and XML Schema and Normative Constraints
1.2V11R1	11/14/11	Accepted changes from Deepak
1.2V11R2	11/15/11	Modifications and corrections from Thomas
1.2V12R1	11/15/11	Corrections and accepted changes from Thomas
1.2V12R2	11/20/11	Corrections, additional normative constraints, submitted changes to controllers by Juergen, updated

		references
1.2V12R3	11/21/11	Accepted changes from V12R2 and corrections from 11/21/11 call.
1.2V12R4	11/07/11	Revisions based on 12/5 phone conference
1.2V15R1	12/19/11	Updated todo list with some accepted changes from 12/15 call
1.2V16R1	12/23/11	Updates based on 12/22/call
1.2V17R1	12/23/11	Feature Complete
10V18R1	01/06/12	Format XML with new tags. Accept changes from Deepak B. and Nick

13 Appendix D: Considerations for Next or Future Releases

ID	Description	Priority
F-0001	Multiple OpenFlow controllers associated with a single OpenFlow capable switch.	P0
F-0002	Adding additional configuration of queue related attributes beyond what is described in OF 1.1 Section A.2.2	
F-0003	OpenFlow Controller configuration and monitoring	
F-0004	bootstrap/auto-discovery/auto-associate of OpenFlow Capable Switches and the OpenFlow Manager
