# A Multi-Task Embedder For Retrieval Augmented LLMs

Anonymous ACL submission

#### Abstract

 LLMs confront inherent limitations in terms of its knowledge, memory, and action. The retrieval augmentation stands as a vital mecha- nism to address these limitations, which brings in useful information from external sources to augment the LLM. However, existing retrieval methods encounter two pressing issues. On one hand, the general retrievers are not prop- erly optimized for retrieval augmentation hence exhibit limited effectiveness; on the other hand, the task-specific retrievers excel in the targeted retrieval augmentation scenario, while lack the versatility to handle diverse scenarios. In this work, we propose LLM-Embedder for the **unified support of diverse retrieval augmen-** tation scenarios. Our method presents three technical contributions. Firstly, we introduce a new *reward formulation*, namely rank-aware reward. It exploits the ranking position of the **desired output among N sampled outputs from**  the LLM, which leads to fine-grained and ro- bust computation of reward from the LLM's feedback. Secondly, we design a novel *distil- lation objective*, called graded distillation. It incorporates both the absolute value and the relative order of the reward for more sufficient utilization of the LLM's feedback. Thirdly, we systematically optimize the *multi-task learning*, which effectively unifies the multiple retrieval functionalities into one model. In our exper- iment, LLM-Embedder notably improves the LLM's performances in various downstream tasks, and outperforms both general and task- specific retrievers with a substantial advantage. erd) optimized for retrievel agentation lence<br>

#### **<sup>035</sup>** 1 Introduction

 Large language models (LLMs) present a unified foundation to support general artificial intelligence applications [\(Brown et al.,](#page-8-0) [2020a;](#page-8-0) [Chowdhery et al.,](#page-9-0) [2022;](#page-9-0) [Touvron et al.,](#page-11-0) [2023\)](#page-11-0). Despite the substan- tial improvement over the last-gen methods, LLMs still face many severe problems, such as halluci-

Figure 1: LLM-Embedder presents a unified embedding model for the diverse retrieval augmentation scenarios.

memory [\(Bai et al.,](#page-8-2) [2023b;](#page-8-2) [An et al.,](#page-8-3) [2023\)](#page-8-3), mis- **043** [f](#page-8-4)ollowing of instructions [\(Ouyang et al.,](#page-10-0) [2022;](#page-10-0) [Bai](#page-8-4) **044** [et al.,](#page-8-4) [2022\)](#page-8-4). Many of the challenges can be traced **045** back to the inherent limitations of LLMs in terms **046** of *knowledge*, *memory*, and *action*. Specifically, **047** LLMs cannot internalize the vast and constantly **048** changed world knowledge due to their finite and **049** static parameters. LLMs are incapable of memo- **050** rizing and utilizing long-term information because **051** of the limited context length. Finally, LLMs re- **052** quire manually in-context examples and tools to **053** accomplish complex real-world tasks. **054**

Retrieval augmentation stands as a vital mech- **055** anism to address these inherent limitations of the **056** LLM. It brings in useful information from exter- **057** nal sources, such as knowledge, memory pieces, **058** in-context examples, and tools, which substantially **059** enhances the LLM for the generation of desired **060** outputs [\(Gao et al.,](#page-9-2) [2023\)](#page-9-2). The embedding model **061** (a.k.a. *embedder*) is a critical part of retrieval aug- **062** mentation, which bridges the LLM's information **063** needs with external sources. The existing embed- **064** ding models can be briefly partitioned into two **065** categories. One is the general-purpose embedders, **066** which aim to be universally applicable for various  $067$ retrieval tasks [\(Izacard et al.,](#page-9-3) [2021;](#page-9-3) [Wang et al.,](#page-11-1) **068** [2022b;](#page-11-1) [Xiao and Liu,](#page-11-2) [2023\)](#page-11-2). Despite their popu- **069**

 larity, they are not properly optimized for retrieval augmentation, and are thus prone to an inferior ef- fectiveness in the corresponding task. The other one is the task-specific embedders, which are tai- lored for one specific retrieval augmentation sce- nario, e.g., knowledge retrieval [\(Yu et al.,](#page-12-0) [2023\)](#page-12-0) and example retrieval [\(Wang et al.,](#page-11-3) [2023a\)](#page-11-3). How- ever, these methods lack versatility across different scenarios. As the LLMs require assistance from diverse external sources in solving real-world prob- lems, it becomes imperative to develop an effective and versatile embedding model to support the di-verse retrieval augmentation needs.

 In this paper, we present LLM-Embedder, a uni- fied embedding model to support a broad range of retrieval augmentation scenarios, including knowl-086 edge retrieval, memory retrieval, example retrieval, and tool retrieval. Training such a versatile embed- ding model presents multiple challenges in terms of 089 1) how to learn from the LLM, and 2) how to harmo- nize different retrieval tasks. In LLM-Embedder, the following technical contributions are presented.

 • **Reward Formulation.** For each retrieval aug- mentation scenario, the embedder is learned from the LLM's feedback, i.e. the retrieval candidate needs to be promoted if it contributes to the gener- ation of the desired output. Conventional methods 097 rely on the generation likelihood [\(Shi et al.,](#page-11-4) [2023;](#page-11-4) [Izacard et al.,](#page-9-4) [2023\)](#page-9-4). However, the absolute gen- eration likelihood tends to fluctuate dramatically, which may lead to inaccurate estimation of the contribution of each retrieval candidate. In LLM- Embedder, we propose a new reward formulation called *rank-aware reward*. Essentially, a retrieval candidate will receive a higher reward if it can bet-105 ter promote the desired output's ranking among N sampled outputs from the LLM. Thus, it is free from dealing with the absolute generation likeli- hood, which facilitates a fine-grained and more robust computation of the reward.

 • Distillation Objective. Based on the LLM's reward, the embedding model is learned by knowl- edge distillation. Typically, this is accomplished by minimizing the KL-divergence between the re- ward distributions and the relevance distribution [e](#page-12-0)stimated by the embedder [\(Shi et al.,](#page-11-4) [2023;](#page-11-4) [Yu](#page-12-0) [et al.,](#page-12-0) [2023\)](#page-12-0). In many cases, the reward distribution are either polarized (extremely high rewards for one candidate while low rewards for others) or flat (even rewards for every candidate), which makes it difficult to distill fine-grained knowledge with KL-Divergence. To address this problem, we de- **121** sign the *graded distillation*. It integrates both the **122** absolute values of rewards and their relative orders **123** for knowledge distillation, which leads to a more **124** sufficient exploitation of the LLM's feedback. **125**

• Multi-task Learning. LLM-Embedder is trained **126** to support diverse retrieval augmentation scenarios **127** through multi-task learning. However, different **128** scenarios need to capture distinct semantic rela- **129** tionships, hence the multiple training tasks may **130** conflict with each other. To harmonize the learning **131** process, we perform systematic optimization with **132** three techniques: 1) *self-paced learning schedul-* **133** *ing*, where lossy tasks can be automatically com- **134** pensated by higher learning rates; 2) *homogeneous* **135** *batching*, where training samples from one com- **136** mon task are gathered in the same batch to optimize **137** the impact of in-batch negative sampling; 3) *diversi-* **138** *fied prompting*, which presents different tasks with **139** unique prefixes such that the embedding model can **140** better distinguish each of them. **141**

To summarize, LLM-Embedder stands as a pi- **142** oneering work for the uniform support of the di- **143** verse retrieval augmentation scenarios of LLMs. It **144** makes threefold technical contributions, and brings 145 valuable inspirations on how to learn from LLM's **146** feedback and how to harmonize different retrieval **147** tasks. In our experiment, LLM-Embedder achieves **148** a superior performance, where it notably improves **149** the LLM's performance in a variety of downstream **150** tasks. Meanwhile, its retrieval augmentation's ef- **151** fect is superior to both general and task-specific **152** retrieval methods. Our model and code will be **153** publicly available to facilitate future research. **154**

#### 2 Related Works **<sup>155</sup>**

• Embedding Model maps the input text into **156** dense vector (i.e. *embedding*) in the semantic **157** space, where the relevance between texts is mea- **158** sured by the similarity between embeddings. It has 159 become the de-facto choice for modern information **160** retrieval systems. There are mainly three research **161** threads for improving the performance of embed- **162** ding models. The first one is leveraging advanced **163** backbone models, including the retrieval oriented **164** models [\(Liu and Shao,](#page-10-1) [2022;](#page-10-1) [Wang et al.,](#page-11-5) [2022a\)](#page-11-5) **165** [a](#page-10-3)nd large language models [\(Ma et al.,](#page-10-2) [2023;](#page-10-2) [Li](#page-10-3) **166** [et al.,](#page-10-3) [2023\)](#page-10-3). Another thread is enhancing the learn- **167** ing methodology, such as upgrading the negative **168** [s](#page-9-3)ampling strategy [\(Karpukhin et al.,](#page-9-5) [2020;](#page-9-5) [Izacard](#page-9-3) 169 [et al.,](#page-9-3) [2021;](#page-9-3) [Xiong et al.,](#page-12-1) [2020\)](#page-12-1) and incorporating **170**  knowledge distillation from a more precise rank- ing model [\(Qu et al.,](#page-11-6) [2020;](#page-11-6) [Hofstätter et al.,](#page-9-6) [2021;](#page-9-6) [Xiao et al.,](#page-12-2) [2022\)](#page-12-2). Last but not least, many recent works dedicate to train a universal retriever across a wide array of tasks [\(Wang et al.,](#page-11-7) [2021;](#page-11-7) [Lewis et al.,](#page-10-4) [2021;](#page-10-4) [Karouzos et al.,](#page-9-7) [2021;](#page-9-7) [Yu et al.,](#page-12-3) [2022;](#page-12-3) [Su](#page-11-8) [et al.,](#page-11-8) [2022;](#page-11-8) [Asai et al.,](#page-8-5) [2022\)](#page-8-5). LLM-Embedder in- herits successful practices for training high-quality dense retriever, while innovating novel techniques to tailor for the multi-task learning of diverse re-trieval augmentation scenarios.

182 • **Retrieval Augmentation** is a vital mechanism to address the inherent limitations of the LLM in terms of knowledge, memory, and action. Con- cretely, the LLM can 1) generate factoid answers [w](#page-9-9)ith retrieved knowledge [\(Gao et al.,](#page-9-8) [2024;](#page-9-8) [Jiang](#page-9-9) [et al.,](#page-9-9) [2023\)](#page-9-9); 2) utilize long-context information with retrieved memory pieces [\(Rubin and Berant,](#page-11-9) [2023;](#page-11-9) [Wang et al.,](#page-11-10) [2023b;](#page-11-10) [Xu et al.,](#page-12-4) [2023\)](#page-12-4); 3) better follow human instruction with retrieved in-context examples [\(Brown et al.,](#page-9-10) [2020b;](#page-9-10) [Cheng et al.,](#page-9-11) [2023\)](#page-9-11); [4](#page-10-5)) execute complex tasks with retrieved tools [\(Qin](#page-10-5) [et al.,](#page-10-5) [2023\)](#page-10-5). In practice, there are two common [o](#page-11-11)ptions of retrievers: the general retrievers [\(Robert-](#page-11-11) [son et al.,](#page-11-11) [2009;](#page-11-11) [Izacard et al.,](#page-9-3) [2021;](#page-9-3) [Xiao and](#page-11-2) [Liu,](#page-11-2) [2023;](#page-11-2) [Neelakantan et al.,](#page-10-6) [2022\)](#page-10-6) and the task-**specific retrievers [\(Yu et al.,](#page-12-0) [2023;](#page-12-0) [Wang et al.,](#page-11-10)**  [2023b;](#page-11-10) [Qin et al.,](#page-10-5) [2023\)](#page-10-5). The general retrievers exhibit superior versatility, but may suffer from an inferior retrieval quality in retrieval augmenta- tion tasks. In contrast, task-specific retrievers are more specialized, achieving better performance in the targeted scenario, while falling short when han- dling other scenarios. Compared with the existing works, LLM-Embedder unifies the generality and specialty: it comprehensively supports all major retrieval augmentation needs of the LLM, mean- while achieving the leading performance in every retrieval augmentation scenario.

**<sup>210</sup>** 3 LLM-Embedder

**211** In this section, we will present the retrieval aug-**212** mentation scenarios with LLM-Embedder (§[3.1\)](#page-2-0), **213** and introduce its training methodology (§[3.2\)](#page-3-0).

#### <span id="page-2-0"></span>**214** 3.1 Retrieval Augmentation

 LLM-Embedder targets on the unified support for the major retrieval augmentation needs of the LLMs, including knowledge retrieval, memory re- trieval, example retrieval, and tool retrieval. It **transforms each retrieval candidate**  $C_i \in \mathcal{C}$  into

<span id="page-2-1"></span>

Figure 2: The rank-aware reward for each retrieval candidate. It measures the improvement of the rank of the desired output among multiple sampled outputs.

its embedding  $C_i \in \mathbb{R}^D$  and stores all embeddings 220 in a vector DB. It also embeds the user input  $U$  221 into  $U \in \mathbb{R}^D$ , then retrieves the top-K relevant 222 candidates based on cosine similarity: **223**

$$
Ret(U) \leftarrow \text{top-}K\{\cos(\boldsymbol{U}, \boldsymbol{C}_i)\}.
$$
 (1) 224

The retrieval result and the user input are synthe- **225** sized with template  $\psi$  to prompt the LLM  $\Theta$ : **226** 

$$
O \leftarrow \Theta(\psi(U, \text{Ret}(U))). \qquad (2) \qquad \qquad \text{227}
$$

Each retrieval augmentation scenario has its unique **228** formulation of retrieval candidate, user input, and **229** prompt template, which are elaborated as follows. **230** • Knowledge Retrieval. The LLM can generate **231** factoid answers with retrieved knowledge. Each **232** retrieval candidate is a passage from an external **233** knowledge corpus. The user input is usually an **234** explicit question. It can also be a conversation **235** context with a context-dependent question. In this **236** case, we concatenate the entire context as the user **237** input. The retrieved passages and the user input are **238** synthesized according to Template [A.1.](#page-13-0) **239** 

• Memory Retrieval. The LLM can remember **240** and utilize long context memory with memory re- **241** trieval [\(Xu et al.,](#page-12-4) [2023\)](#page-12-4). Specifically, the long **242** context split into equal-size chunks  $\{v_1, \ldots, v_n\}$ . 243 When processing the  $v_j$ , each previous chunk con-  $244$ catenated with its subsequent chunk is treated as **245** a retrieval candidate, i.e.  $C_i \leftarrow v_i + v_{i+1}, i < j.$  246 The user input is  $v_i$  itself. Denote the LLM's con-  $247$ text window size as  $L^*$ . We maintain the recent  $L$  248

tokens in the context window, while the rest  $L^* - L$ **250** are populated with retrieved chunks.

 • Example Retrieval. In-context examples help the LLM to better follow human instruction. In- stead of relying on manual specification, in-context examples can be retrieved automatically to improve the performance. Each example contains an op- tional task description, an input, and an output, which are all concatenated to form a retrieval can- didate. The user input is the concatenation of the task description and the task-specific input. The re- trieved examples and the user input are synthesized with Template [A.5](#page-13-1) to feed into the LLM.

 • Tool Retrieval. The LLM leverages tools to execute complex real-world tasks [\(Qin et al.,](#page-10-5) [2023;](#page-10-5) [Yao et al.,](#page-12-5) [2023\)](#page-12-5). Tool retrieval efficiently provides useful tools for the LLM. The tool's description and its API are concatenated as the retrieval candidate. The user's request is treated as the user input.

# <span id="page-3-0"></span>**268** 3.2 Training Methodology

# **269** 3.2.1 Reward Formulation

 A retrieval candidate is useful if it can facilitate the generation of the desired output (denoted as  $O<sup>*</sup>$ ). The absolute value of generation likelihood is not an appropriate measurement because it is prone to dramatic numerical fluctuations. Alter- natively, as shown in Figure [2,](#page-2-1) we argue that a retrieval candidate is useful if it can lead to a better ranking position of the desired output among N **Sampled outputs from the LLM's (** $\{O_i\}_{i=1}^N$ **). Based**  on this argument, we descendingly sort the sam- pled outputs based their generation likelihoods and compute the rank of the desired output among them when retrieval is disabled:

283 
$$
r^a \leftarrow \operatorname{rank}_{O^*}(\{O_1,\ldots,O_N:\ O_i \sim \Theta(U)\}).
$$

**284** We then compute the rank of the desired output **285** with the same operation except that the retrieval **286** augmentation is enabled:

$$
r^{b} \leftarrow \operatorname{rank}(\{O_1, \ldots, O_N : O_i \sim \Theta(\psi(U, C_i))\})
$$

Finally, the reward for the retrieval candidate  $C_i$  is **289** computed as its improvement of the rank:

$$
R(C_i) \leftarrow r^a - r^b. \tag{3}
$$

 This reward formulation is free of dealing with absolute likelihood values, but focuses on the re- trieval candidate's real impact on facilitating the generation of the desired output.

# 3.2.2 Distillation Objective **295**

Based on the LLM's rewards, the embedding model **296** is learned through knowledge distillation, so that **297** the relevance estimated by the embedder becomes **298** consistent with the retrieval candidate's actual use- **299** fulness. Minimizing KL-Divergence between the **300** relevance distribution and the reward distribution is **301** [t](#page-9-4)he most typical approach [\(Shi et al.,](#page-11-4) [2023;](#page-11-4) [Izacard](#page-9-4) **302** [et al.,](#page-9-4) [2023;](#page-9-4) [Yu et al.,](#page-12-0) [2023\)](#page-12-0). However, the reward **303** distribution sometimes exhibits polarized (substan- **304** tially high reward for one candidate while low for **305** others) or flat (even reward for each candidate) pat- **306** terns. The KL-Divergence cannot effectively distill **307** fine-grained knowledge from these distributions. **308** To address this problem, we innovate a *graded* **309** *distillation* objective, which integrates both the ab- **310** solute reward values and the relative reward orders **311** for learning. It consists of a series of contrastive **312** losses, where the negatives of each loss include the **313** lower-rewarded candidates and the in-batch candi- **314** dates. All contrastive losses are aggregated with **315** normalized rewards as weights. Formally, given the **316** retrieval candidates  $\{C_i\}_{i=1}^M$ , their normalized re- 317 wards  $w(C_i) \leftarrow \text{softmax}(R(C_*))[i]$ , the objective 318 is formulated as: **319**

$$
\mathcal{N}(C_i) \leftarrow \{C: R(C) < R(C_i)\} \cup \text{InBatch}(C_i), \tag{320}
$$
\n
$$
\sum_{c \text{cos}(U, C_i)} \text{cos}(U, C_i)
$$

$$
\min \sum_{C_i} -w(C_i) \log \frac{e^{\cos(U, C_i)}}{\sum_{C' \in \mathcal{N}(C_i)} e^{\cos(U, C')}}.
$$
 (4)

. (4) **321**

The graded distillation objective enjoys two advan- **322** tages. On one hand, it can robustly optimize the **323** embedder from various reward distributions. For **324** the polarized rewards, it will become the one-hot **325** contrastive learning. For the flat rewards, it will al- **326** ways supervise the embedder to prioritize the more **327** useful candidates against the less useful ones, re- **328** gardless of the absolute value of the reward. On **329** the other hand, it incorporates in-batch negatives **330** in the training process, which further improves the **331** discrimination capability of the embedder. **332**

# 3.2.3 Multi-Task Learning **333**

LLM-Embedder learns to support the four retrieval **334** augmentation needs with a single model through **335** multi-task learning. Different retrieval tasks call for **336** distinct semantic relationships, which may conflict **337** with each other. Therefore, it's important to distin- 338 guish these tasks and harmonize the their learning **339** process. In this place, we tailor the multi-task learn- **340** ing framework with three techniques. **341**

 • Self-Paced Learning Scheduling. The intrinsic learning difficulty of each task may vary, poten- tially leading to differences in the model's learn- ing pace for each task. This may result in the over-optimization of simpler tasks and the under- optimization of more challenging tasks. Inspired by [\(Liu et al.,](#page-10-7) [2019\)](#page-10-7), we propose to dynamically adjust the learning pace of each retrieval task to address this problem. Specifically, we deem the loss of each retrieval task as a proxy to the learning condition of that task. Based on it, we amplify the learning rate for lossy tasks and reduce the learning rate for already learned tasks. To achieve this goal, we periodically checkpoint the loss of retrieval task  $T$  during training, denoted as  $L_0^T$ . Given the basic learning rate  $\alpha$ , and the current loss of the retrieval task T, the learning rate of the current optimization 359 step is set to  $\alpha \times \sqrt{\frac{L^T}{L_0^T}}$ .

 • Homogeneous Batching. The embedding model's discrimination capability benefits from the [q](#page-9-3)uality and quantity of negative samples [\(Izacard](#page-9-3) [et al.,](#page-9-3) [2021;](#page-9-3) [Wang et al.,](#page-11-1) [2022b\)](#page-11-1), which consist of hard negatives and in-batch negatives. The vanilla batching strategy often packs training samples from different tasks in the same batch. These samples are irrelevant to each other and hence adversely influence the quality of in-batch negatives. Instead, we gather the training samples from the same re- trieval task to form every batch. In this way, LLM- Embedder should discriminate the positive sample 372 against  $B \times M \times Z - 1$  negatives from the same retrieval task, where B is the batch size, M the candidate number, and Z the GPU number.

 • Diversified Prompting. For retrieval task T, **two unique instructions**  $I_U^T$ **,**  $I_C^T$  **are assigned, which**  are prefixed to the user input and the retrieval can- didate, respectively. The concatenated sequence is encoded into its embedding by LLM-Embedder:

$$
U^T \leftarrow \text{encode}(I_U^T + U), \ \ \mathbf{C}_i^T \leftarrow \text{encode}(I_C^T + C_i).
$$

381 **The resulting embedding**  $U^T$  **and**  $C_i^T$  **are differen-382** tiated across tasks, which helps LLM-Embedder to **383** distinguish each task.

#### **<sup>384</sup>** 4 Experiment

 The experimental studies aim to investigate three research questions. *RQ 1.* Can LLM-Embedder support the LLM's diverse retrieval augmentation need? (§[4.2\)](#page-5-0) *RQ 2.* What is LLM-Embedder's impact on each retrieval augmentation scenario? (§[4.3\)](#page-6-0) *RQ 3.* What is the individual contribution of **390** each technique in LLM-Embedder? (§[4.4\)](#page-7-0) **391**

#### 4.1 Settings **392**

### **4.1.1 Training & Evaluation** 393

We introduce the details of training and evaluation 394 on the four retrieval augmentation scenarios. Statis- **395** tics of all training datasets are reported in Table [7.](#page-15-0) **396** • Knowledge Retrieval. We train LLM-Embedder **397** with three datasets for knowledge retrieval, in-<br>398 cluding MSMARCO [\(Nguyen et al.,](#page-10-8) [2016\)](#page-10-8), Nat- **399** ural Questions [\(Kwiatkowski et al.,](#page-10-9) [2019\)](#page-10-9), and **400** QReCC [\(Anantha et al.,](#page-8-6) [2020\)](#page-8-6). Note that QReCC **401** does not have well-formed answers for generat- **402** ing rewards, thus, we use the annotated relevance **403** for contrastive learning. We include three datasets **404** to evaluate the impact of knowledge retrieval. 1) **405** MMLU [\(Hendrycks et al.,](#page-9-12) [2020\)](#page-9-12), a multiple-choice **406** questions dataset that covers a wide range of knowl- **407** edge. We retrieve 3 passages from the MSMARCO **408** Passage corpus [\(Nguyen et al.,](#page-10-8) [2016\)](#page-10-8), which are integrated as a prompt with the official Template [A.2.](#page-13-2) **410** The metric is accuracy. 2) PopQA [\(Mallen et al.,](#page-10-10) 411 [2022\)](#page-10-10), a question answering dataset that focuses **412** on long-tail entities. We retrieve 3 passages from **413** Wikipedia [\(Karpukhin et al.,](#page-9-5) [2020\)](#page-9-5), which are inte- **414** grated with the official Template [A.3.](#page-13-3) The met- **415** ric is exact match. 3) QReCC [\(Anantha et al.,](#page-8-6) **416** [2020\)](#page-8-6), a conversational search dataset that requires **417** the retriever to find the relevant passage accord- **418** ing to a conversation context. It already provides **419** the ground-truth passage, we directly evaluate the **420** ranking metric, i.e. NDCG@3 following previous **421** works [\(Mao et al.,](#page-10-11) [2023\)](#page-10-11). **422**

• Memory Retrieval. We consider two tasks **423** for memory retrieval. 1) Long-context conversa- **424** tion with MSC [\(Xu et al.,](#page-12-6) [2021\)](#page-12-6), where the LLM **425** should generate the ground-truth response. We **426** retrieve 1 historical dialogue turn as additional con- **427** text, which is synthesized with Template [A.4.](#page-13-4) We **428** use its training set to fine-tune LLM-Embedder. 2) **429** [L](#page-9-13)ong-range language modeling with Books3 [\(Gao](#page-9-13) **430** [et al.,](#page-9-13) [2020\)](#page-9-13), ArXiv [\(Gao et al.,](#page-9-13) [2020\)](#page-9-13), CodePar- **431** rot [\(Tunstall et al.,](#page-11-12) [2022\)](#page-11-12), and PG19 [\(Rae et al.,](#page-11-13) **432** [2019\)](#page-11-13), where PG19 is held-out from training. We **433** set the chunk size to 128, and maintain a recent 434 context length of 2048. We retrieve 8 chunks and **435** their continuation chunk to prepend to the recent **436** context. Perplexity is the metric for both tasks. **437**

[•](#page-11-3) Example Retrieval. We follow LLM-R [\(Wang](#page-11-3) **438** [et al.,](#page-11-3) [2023a\)](#page-11-3) to use in-context learning tasks from **439**  FLAN [\(Chung et al.,](#page-9-14) [2022\)](#page-9-14) for training and eval- uating the impact of example retrieval. It consists of 9 distinct categories with 30 datasets: Closed- Book QA (CQA), Commonsense (Comm), Corefer- ence (Coref), Paraphrase (Para), Natural Language Inference (NLI), Reading Comprehension (RC), Sentiment Analysis (Sent), Data2Text (D2T), Sum- marization (Summ). We retrieve 8 examples from the union of the training set examples, which are synthesized with Template [A.5.](#page-13-1) The evaluation metric is specified in Table [6.](#page-14-0)

[•](#page-10-5) **Tool Retrieval.** We use the ToolBench [\(Qin](#page-10-5) [et al.,](#page-10-5) [2023\)](#page-10-5) for training and evaluating the tool retrieval performance. Akin to QReCC, this dataset does not include desired output from the LLM, hence we train LLM-Embedder with contrastive loss and directly evaluate NDCG@5.

#### **457** 4.1.2 Baselines

 Firstly, we measure the performance of the LLM without retrieval augmentation, denoted as *None*. Secondly, we compare with two types of retrievers. 1) *General retrievers*, which aim to support a wide range of text retrieval and representation tasks, such as question answering, entity retrieval, and dupli- cation detection. We include the following widely- recognized baselines: BM25 [\(Robertson et al.,](#page-11-11) [2009\)](#page-11-11), Contriever [\(Izacard et al.,](#page-9-3) [2021\)](#page-9-3), Instruc- [t](#page-10-1)or [\(Su et al.,](#page-11-8) [2022\)](#page-11-8), RetroMAE-BEIR [\(Liu and](#page-10-1) [Shao,](#page-10-1) [2022\)](#page-10-1), and BGE [\(Xiao and Liu,](#page-11-2) [2023\)](#page-11-2). These methods are empirically competitive according to [B](#page-10-12)EIR [\(Thakur et al.,](#page-11-14) [2021\)](#page-11-14) and MTEB [\(Muen-](#page-10-12) [nighoff et al.,](#page-10-12) [2022\)](#page-10-12) benchmarks. 2) *Task-specific embedding models*. These models are optimized for one specific retrieval augmentation scenario. We include the following baselines that excel in their respective scenario: ARR [\(Yu et al.,](#page-12-0) [2023\)](#page-12-0) for knowledge retrieval, LLM-R [\(Wang et al.,](#page-11-3) [2023a\)](#page-11-3) for example retrieval, and API-Retriever [\(Qin et al.,](#page-10-5) [2023\)](#page-10-5) for tool retrieval. Since retrieval augmenta- tion introduces additional context to the LLM, we add a simple yet strong baseline called *Recency* for memory retrieval. It directly extends the context window by the length of retrieved context.

# **483** 4.1.3 Implementation

 We use Llama-2-7B-Chat [\(Touvron et al.,](#page-11-0) [2023\)](#page-11-0) as the backbone LLM. Besides, we utilize BGE base [\(Xiao and Liu,](#page-11-2) [2023\)](#page-11-2) to initialize LLM- Embedder and fine-tune it as described in §[3.2.](#page-3-0) The hyper parameters during fine-tuning are shown in Table [9.](#page-16-0) Although using rewards from Llama-2 7B

<span id="page-5-1"></span>

Figure 3: Impact of retrieval augmentation from different retrievers (metric values are min-max normalized).

Chat, LLM-Embedder is also applicable to other **490** LLMs and its advantage remains. The experimental **491** results are shown in Appedix [D.](#page-13-5) We use Flat index **492** from faiss [\(Johnson et al.,](#page-9-15) [2019\)](#page-9-15) for searching. **493**

#### <span id="page-5-0"></span>4.2 Overall Analysis **494**

The evaluation results of the four retrieval augmen- **495** tation scenarios are presented in Table [1-](#page-6-1)[3.](#page-7-1) **496**

Firstly, compared with the results without re- **497** trieval augmentation, i.e. None, LLM-Embedder **498** delivers more precise answers with the retrieved **499** knowledge (Table [1\)](#page-6-1), improved quality of long- **500** sequence generation with the retrieved memory 501 (Table [2\)](#page-6-2), better instruction following effect with **502** the retrieved examples (Table [3\)](#page-7-1), and more accu- **503** rate tool retrieval (Table [3\)](#page-7-1). Besides, though the **504** LLM's performance can also by improved by other **505** baseline retrievers, LLM-Embedder always leads **506** to the most amplified retrieval augmentation ef- **507** fect across all scenarios. It outperforms all general **508** retrievers and is competitive against task-specific **509** retrievers, i.e. AAR for knowledge enhancement, **510** LLM-R for example retrieval, and API-Retriever **511** for tool retrieval. This observation validates that **512** *the LLM benefits from the retrieved information;* **513** *meanwhile, LLM-Embedder can provide a strong* **514** *and unified foundation to support diverse retrieval* **515** *augmentation needs of the LLM*. **516**

We can also observe that the task-specific em-  $517$ bedders optimized for one scenario result in lim- **518** ited performances in others, suggesting that the se- **519** mantic relationships required by different retrieval **520** scenarios are not transferable. To better illustrate **521** this point, we visualize the retrieval augmenta- **522** tion's impact from five representative methods in **523** Figure [3.](#page-5-1) Notably, although task-specific embed- **524** ders exhibit competitive performance for their tar- **525** geted scenario, their impacts are severely weakened **526** when applied on other scenarios. In contrast, LLM-  $527$

Table 2: The impact of memory retrieval. Recency is to directly extend the context without retrieval.

 Embedder demonstrates a steady and competitive performance across all scenarios. To summarize, *the irrelevant or even adverse retrieval patterns can be reconciled by one unified embedding model on top of our optimized training methodology*.

#### <span id="page-6-0"></span>**533** 4.3 Individualized Analysis

 • Knowledge Retrieval. The evaluation results of knowledge retrieval are reported in Table [1.](#page-6-1) We make the following observations. 1) Benefit of ex- ternal knowledge. On both MMLU and PopQA, we can observe significant empirical advantages of the retrieval augmentation methods compared with the plain LLM, i.e. None. Among all retrieval methods, LLM-Embedder is able to return the most accuracy knowledge, leading to the best retrieval augmenta- tion effect on both datasets. 2) Distinction among datasets. The impact of knowledge retrieval is more noticeable on PopQA than MMLU. This is because PopQA is more knowledge-intensive, with a focus on questions about long-tail entities. Moreover, the baseline embedding models fail to handle conver- sational search queries, resulting in their inferior NDCG compared with BM25 on QReCC. In con-trast, LLM-Embedder significantly outperfoms all baselines on QReCC, again verifying its versatility. **552**

• Memory Retrieval. The evaluation results of **553** memory retrieval are reported in Table [2.](#page-6-2) On one **554** hand, baseline retrievers underperform the Recency **555** baseline on MSC, which translates to the negative **556** impact of the retrieved conversation compared with **557** the recent one. This observation underscores the **558** challenges in effective memory retrieval. On the **559** other hand, the LLM-Embedder retains its superior **560** performance, reducing the perplexity against the **561** all baseline methods on all datasets. **562**

• Example Retrieval. The evaluation results of **563** example retrieval are reported in Table [3.](#page-7-1) We have **564** the following observations. 1) Compared with ran- **565** dom examples, using retrieved examples yields **566** improved performances in most cases. This find- **567** ing underscores the effect of example retrieval for **568** helping the LLM to properly follow instructions.  $569$ 2) BM25's performance is substantially weaker **570** than its performance in other scenarios. This dis- **571** crepancy can be attributed to the specific nature **572** of in-context learning, where useful examples may **573** have low lexical similarity with the user input. **574**

• Tool Retrieval. The evaluation results of exam- **575** ple retrieval are reported in Table [3.](#page-7-1) We observe **576**

w.o. Diversified Instruction	0.503	13.942	0.619	0.828

Table 4: Ablation studies of LLM-Embedder.

 that the task-specific method, i.e. the API retriever, beats other baseline methods by a large margin. This is because these baselines are unfamiliar with tools and hence fail to properly estimate the rel- evance. However, LLM-Embedder continues to maintain the leading position, highlighting its un-fied support for diverse retrieval tasks.

#### <span id="page-7-0"></span>**584** 4.4 Ablation Studies

**585** The ablation studies are performed to to evaluate **586** the impact from each technical factor. The evalua-**587** tion results are reported in Table [4.](#page-7-2)

 For "*w.o. Rank-Aware Reward*", we switch to the [t](#page-11-4)ypical likelihood-based reward formulation [\(Shi](#page-11-4) [et al.,](#page-11-4) [2023\)](#page-11-4). Notably, the performance on knowl- edge retrieval and memory retrieval substantially decreases. We conjecture that in both scenarios, the generation likelihood of the desired output drasti- cally fluctuate, resulting in the inaccurate measure-ment of the retrieval candidate's usefulness.

 For "*w.o. Graded Distillation*", the graded dis- tillation objective is replaced by the typical KL- divergence [\(Izacard et al.,](#page-9-4) [2023\)](#page-9-4). As introduced, graded distillation can stay robust to the polarized or flat rewards, which leads to more effective us- age of the LLM's feedback. In this place, we can observed that LLM-Embedder's performance is re- duced when graded distillation is disabled, espe-cially for example retrieval.

**605** For "*w.o. Self-Paced Scheduling*", the learning **606** rate is the kept static for all retrieval tasks during fine-tuning. We can observe that the performance **607** of tool retrieval drops significantly. This is because **608** the learning for this scenario does not proceed at **609** the same pace as other scenarios, necessitating the **610** dynamic control over learning speed for different **611** retrieval tasks. **612**

For "*w.o. Homogeneous Negatives*", the ho- **613** mogeneous in-batch negatives are disabled. This **614** change reduces the discrimination capability of the **615** embedder, because a great portion of the in-batch **616** negative samples will come from different tasks, **617** which are irrelevant to the target one. As we can ob- **618** serve, LLM-Embedder's performance is decreased **619** due to such a change, especially for knowledge re- **620** trieval, where LLM-Embedder should discriminate **621** the relevant passage from a massive corpus. **622**

For "*w.o. Diversified Instruction*", we remove **623** the task-specific instructions in fine-tuning and **624** evaluation. Without this technique, it becomes **625** harder for the embedding model to distinguish dif- **626** ferent retrieval tasks. This intuition is consistent **627** with the observed result, as LLM-Embedder's per- **628** formance decreases across all tasks. **629**

#### 5 Conclusion **<sup>630</sup>**

In this work, we present LLM-Embedder, a unified **631** embedding model to support the LLM's diverse **632** retrieval augmentation needs, including knowledge **633** retrieval, memory retrieval, example retrieval, and **634** tool retrieval. We propose three key techniques to **635** facilitate the training of LLM-Embedder, spanning **636** from reward formulation, distillation objective, and **637** multi-task learning recipe. Our experiments show **638** LLM-Embedder's empirical advantages over both **639** general and task-specific embedding models across **640** all evaluation scenarios. This highlights its effec- **641** tiveness as a foundational building block to support **642** the retrieval augmentation of the LLM. **643**

# **<sup>644</sup>** 6 Limitations

 A few recent studies incorporate large language models as the embedding backbone and achieve new state-of-the-art performance. However, LLM- Embedder is a BERT-base scale model. Its scal- ing effect remains unexplored. Besides, LLM- Embedder is specifically tailored for the four re- trieval scenarios. For tasks that fall outside its scope of coverage, such as documentation retrieval, the effectiveness of the LLM-Embedder may not be as robust as that of a strong general embedding model like BGE.

# **<sup>656</sup>** 7 Ethical Considerations

 LLM-Embedder is an embedding model that maps the text into high-dimensional vectors and relies on vector similarity to determine relevance between texts. Therefore, it inherits the potential risks of the embedding model family. Specifically, LLM- Embedder may process a large amount of personal or sensitive data, which must be handled with con- sent. There is also the security concern as recent works have proven it possible to decrypt the orig- inal textual information from embedded vectors. Lastly, it may perpetuate and amplify biases present in the training data, leading to unfair or discrimina-tory outcomes.

<Input>

# **<sup>1147</sup>** B Dataset Details

 The detailed information of in-context learning datasets is reported in Table [6.](#page-14-0) The statistics of all training and evaluation datasets are reported in Table [7.](#page-15-0) The average lengths of long-range lan-guage modeling datasets are reported in Table [5.](#page-13-6)

<span id="page-13-6"></span>

Table 5: Average lengths of long-range language modeling datasets.

# C Implementation Details **<sup>1153</sup>**

#### C.1 Instructions **1154**

The instructions used for each retrieval task are **1155** shown in Table [8.](#page-15-1) **1156** 

#### C.2 Training Settings **1157**

The hyper parameter settings for training LLM- **1158** Embedder are reported in Table [9.](#page-16-0) **1159** 

# <span id="page-13-5"></span>D Impact of LLM-Embedder on **<sup>1160</sup> Different LLMs** 1161

We evaluate the impact of LLM-Embedder when 1162 augmenting different LLMs to validate its gener- **1163** alization ability. Specifically, we utilize Aquila- **1164** 7B-Chat [\(Aqu,](#page-8-7) [2023\)](#page-8-7), Qwen-7B-Chat [\(Bai et al.,](#page-8-8) **1165** [2023a\)](#page-8-8), Baichuan2-7B-Chat [\(Baichuan,](#page-8-9) [2023\)](#page-8-9), and **1166** Llama-2-13B-Chat [\(Touvron et al.,](#page-11-0) [2023\)](#page-11-0). The re- **1167** sults are shown in Table [10.](#page-16-1) We report the average 1168 accuracy for MMLU, accuracy for PopQA, the av- **1169** erage score for in-context learning, and perplexity **1170** for both Multi-Session Chat and Arxiv. Note that **1171** we do not replicate the evaluation of tool learn- **1172** ing and conversational search because their perfor- **1173** mances are directly measured by retrieval metrics. 1174

We can observe that our conclusions in Sec- 1175 tion [4.2](#page-5-0) still hold. First of all, retrieval from the ex- **1176** ternal world benefits LLM's performance in all four **1177** scenarios, since the performance of the plain LLM 1178 (i.e. None) underperforms retrieval-augmented one **1179** (BGE and LLM-Embedder). Besides, our proposed **1180** LLM-Embedder is able to generalize well to other **1181** LLMs and maintain its superiority over BGE on **1182** most datasets (PopQA and ICL in particular). This **1183** observation highlights the practical effectiveness **1184** and versatility of LLM-Embedder. **1185**

**1144**

**1145**

**1146**
