Abstract—This paper studies the rate maximization problem of a Full duplex(FD) D2D underlying cellular network. In the considered scenario, multiple FD-D2D pairs coexist with multiple cellular users which generate mutual interference between the two communication types. The complicated interference environment makes the optimization problem a non-concave problem. To solve this problem, we discuss how to leverage the monotonic optimization theory to obtain the global optimal solution at the cost of high complexity. We also derive a geometric based optimization framework, denoted as GALEN, that achieves the global optimality with much lower complexity, and also it provides a closed form expression for the solution. The simulation results show the importance of the proposed solution. **Index Terms**—full-duplex transmission, device-to-device (D2D) communication, optimal power allocation, duplex mode selection

I. INTRODUCTION

Given the scarcity property of the cellular radio spectrum, coupled with the rapidly growing of the users' data traffic demands [1], the need of new technologies which efficiently use the radio resources and fulfill the customers' demands has become an essential part in the upcoming cellular network (5G). In this context, Full Duplex (FD) and device-to-device (D2D) communication are proposed to enhance the radio spectrum efficiency and the users' experience in a cellular network. D2D allows two nearby devices to bypass the base station (BS) and communicate directly peer-to-peer as a D2D communication pair [2]. On the other hand, FD allows a device to simultaneously transmit and receive in the same frequency band at the same time slot [3].

Due to the short distance feature of the D2D communication, integrating the FD technology with D2D communication can further enhance the radio spectrum efficiency and the users' throughput [4]. However, the practical FD devices add new challenges on both the D2D communication and the traditional cellular communication. For instance, the existing FD transceivers can not perfectly remove the self interference (SI) imposed on the receiver by the node's own transmitter [3]. Thus, the residual self interference (RSI) which is tightly related to the transmitter power value highly affects the performance of FD transmission. In addition, using the FD

technique creates additional interference in the network which may overwhelm the conventional cellular link. Thus, a proper power allocation is needed to exploit the benefits of FD and guarantee the quality of service (QoS) of the users.

The authors of [5] tackled the power allocation problem of an isolated full duplex D2D pair operating on the cellular resources. Motivated by the work of [5], the authors of [6] aimed to maximize the throughput of a FD-D2D link by properly allocating the power of the D2D pair and the CU while satisfying the minimum rate requirement of the CU. The ergodic rate of a FD-D2D pair coexisting with a CU was derived and analysed in [7] considering a fixed transmission power strategy. The authors of [8] proposed to maximize the ergodic sum-rate of a FD-D2D pair underlying cellular network while satisfying the data-rate requirement of the CUs. In [9], a power allocation solution was proposed by using the DC programming theory [10]. However, none of the above works provided a global optimal power allocation scheme. Indeed, due to the complicated interference environment generated by the FD transmission, the power allocation is a non-concave problem. Thus finding the global optimal solution is a challenging task. Instead, a first-order optimal solution was given in literature (e.g. [9]), or a sub-optimal solution was provided as in [5], [7], [8].

In this paper, we aim at providing the global optimal solution of the rate maximization problem of a FD-D2D network. To that end, we develop two novel optimization frameworks for a FD-D2D underlying cellular network. The former provides the global optimal solution by means of monotonic optimization theory (MO) [11], [12] at the expense of high complexity, whereas the latter achieved the global optimality by exploiting the geometric structure of the feasible set with much reduced complexity. For the sake of readability, we named the second approach GALEN (Geometrical framework Approach for gLobal optimal powEr allocation). The major contribution of this work are as follows:

- Shedding the light on the optimal rate gain of a FD-D2D network
- Providing two approaches that lead to the global optimal

solution. To the best of the authors knowledge, none of the existing works provides the global optimal solution of a FD-D2D network. Global optimality is achieved by exploiting the MO theory and developing a new geometric based optimization framework.

- Providing a closed form expression for the optimal power allocation
- Highlighting the impact of the SI cancellation factor and the D2D proximity distance on the throughput gain.

The rest of this paper is organized as follows. Section II describes the system model and formulates the optimization problem. Section III derives the optimal solution by using the MO theory while section IV derives the optimal solution by using the geometric structure of the feasible set. The simulation results are given in section V, and finally, the conclusion is drawn in section VI.

II. SYSTEM MODEL AND PROBLEM FORMULATION

We consider a D2D communication underlaying cellular network where M FD-D2D pairs coexist with M half duplex cellular users. Without loss of generality, we will consider in this work that each D2D pair will share the same resources as an uplink CU resource. We will denote that resource as j . In other words, Each D2D pair $D2D_j$ consists of two nearby devices, denoted as D_1^j and D_2^j , that have been assigned the uplink (UL) resources of the j th cellular users (CU_j). UL sharing is particularly considered since the UL resources are underutilized compared to that of downlink. Furthermore, sharing the UL spectrum only affects the BS and incurred interference can be handled by BS coordination.

An instance of this network is drawn in Fig.1 in which two D2D pairs coexist with two cellular users ($M = 2$). The channel gain between the j th cellular user and the BS is denoted as $g_{c,bs}^j$ while the channel gain between D_1^j and D_2^j and between D_2^j and D_1^j are denoted as g_d . $h_{d1,bs}^j$ and $h_{d2,bs}^j$ respectively denotes the interference channel gains from D_1^j and D_2^j to BS. $h_{c,d1}^j$ and $h_{c,d2}^j$ denotes the interference channel gains from the j th cellular user to D_1^j and D_2^j respectively. All direct/interference channels are assumed to be zero-mean complex Gaussian random variables (i.e., channels are expressing Rayleigh fading) with variance l_{ij} , where $i \in \{c; d1; d2\}$, $j \in \{bs; d1; d2\}$, $i \neq j$, l_{ij} denotes the distance between the nodes i and j , and α denotes the path loss exponent. $h_{1,1}^j$ and $h_{2,2}^j$ stands for the residual self interference at D_1^j and D_2^j . They can be modeled as complex Gaussian random variables with zero-mean and variance ηP_{d1}^j and ηP_{d2}^j respectively [5], [6], [13], where P_{d1}^j and P_{d2}^j are respectively the transmission power of D_1^j and D_2^j , η denotes the SI cancellation capability of each D2D device.

A. Full duplex D2D link's rate

In the FD D2D communication mode, both D_1^j and D_2^j reuse the spectrum of CU_j to communicate with each other. By denoting N_0 the power of the additive white Gaussian noise, and P_c^j the transmission power of the j th cellular user

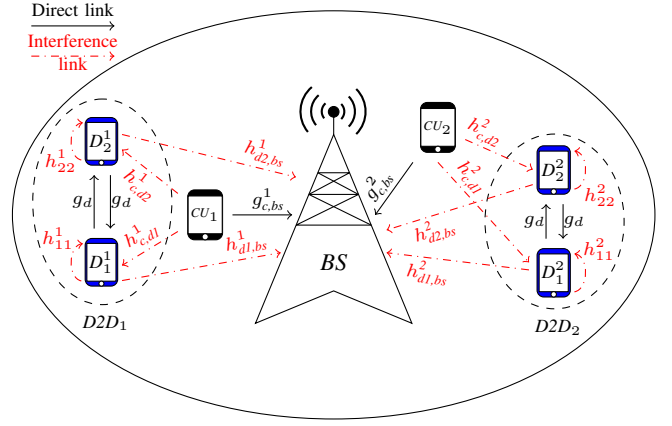

Fig. 1. Full duplex D2D pairs sharing the UL resources of the cellular users. then the received signal to interference plus noise ratio (SINR) at the BS, at D_1^j and at D_2^j when $D2D_j$ shares the spectrum of CU_j can be respectively expressed as

$$\Gamma_{bs}^j = \frac{P_c^j g_{c,bs}^j}{P_{d1}^j h_{d1,bs}^j + P_{d2}^j h_{d2,bs}^j + N_0} \quad (1)$$

$$\Gamma_{d1}^j = \frac{P_{d2}^j g_d^j}{P_c^j h_{c,d1}^j + \eta P_{d1}^j + N_0} \quad (2)$$

$$\Gamma_{d2}^j = \frac{P_{d1}^j g_d^j}{P_c^j h_{c,d2}^j + \eta P_{d2}^j + N_0} \quad (3)$$

Applying Shannon theorem, the rate of $D2D_j$ (R_{fd}^j) can be expressed as the summation of D_1^j 's rate (R_{d1}^j) and D_2^j 's rate (R_{d2}^j).

$$R_{fd}^j(\mathbf{p}_j) = \underbrace{B_j \log_2(1 + \Gamma_{d1}^j)}_{R_{d1}^j} + \underbrace{B_j \log_2(1 + \Gamma_{d2}^j)}_{R_{d2}^j} \quad (4)$$

with $\mathbf{p}_j = (P_{d1}^j, P_{d2}^j, P_c^j)$ being the transmission power of the couple ($D2D_j, CU_j$). B_j denotes the bandwidth of CU_j which is reused by $D2D_j$.

B. Problem formulation

The main rationale behind introducing D2D communications is to mitigate the heavy data traffic in the cellular network. In this paper, we aim at maximizing the total D2D capacity while satisfying the QoS of the cellular users¹. Let r_{\min}^j be the minimum data rate of CU_j , and denote by $\mathbf{P} = [\mathbf{p}_j]_{M \times 3}$ the matrix of the users' transmission power, the D2D sum-rate maximization problem can be formulated as

$$\mathbf{PI} : \max_{\mathbf{P}} \sum_{j=1}^M R_{fd}^j \text{ s.t. } \mathbf{P} \in \Phi \quad (5)$$

$$\Phi = \{\Gamma_{bs}^j \geq \gamma_{\min}^j = 2^{r_{\min}^j} - 1, j \in \{1, \dots, M\}\} \quad (6)$$

$$0 \leq P_i^j \leq P_{\max}^i, i \in \{d1, d2, c\}, j \in \{1, \dots, M\},$$

where P_{\max}^i is the maximum transmission power of a transmitter i , and γ_{\min}^j is the minimum required SINR level to achieve r_{\min}^j . Solving \mathbf{PI} is the target of the next section.

¹The QoS of the CU sharing the resource might be highly constrained

C. Reformulation of problem **P1**

First we observe that the couples $(D2D_j, CU_j)$, $j \in \{1, \dots, M\}$, are independent from each others, and thus **P1** can be rewritten as:

$$\mathbf{P2} : \sum_{j=1}^M \max_{\mathbf{p}_j} R_{fd}^j \text{ s.t. } \mathbf{p}_j \in \Phi. \quad (7)$$

Next, by using the Logarithm's properties, we rewrite R_{fd}^j as:

$$R_{fd}^j(\mathbf{p}_j) = B_j \log_2(Q_j(\mathbf{p}_j)) = B_j \log_2\left((1 + \Gamma_{d1}^j)(1 + \Gamma_{d2}^j)\right). \quad (8)$$

The Logarithm is a monotonic increasing function, and thus maximizing $R_{fd}^j(\mathbf{p}_j)$ is equivalent to maximize $Q_j(\mathbf{p}_j)$. Therefore, **P2** can be equivalently written as:

$$\mathbf{P3} : \sum_{j=1}^M R_{fd}^j(\mathbf{p}_j^*) \quad (9)$$

$$\text{such that } \mathbf{p}_j^* = \operatorname{argmax}_{\mathbf{p}_j \in \Phi} Q_j(\mathbf{p}_j) \quad (10)$$

with $\mathbf{p}_j^* = (P_{d1}^{j,*}, P_{d1}^{j,*}, P_c^{j,*})$ being the optimal power allocation vector for the couple $(D2D_j, CU_j)$.

Now, observe that $Q_j(\mathbf{p}_j)$ is a non-concave function (since it is the multiplication of two linear fractional functions). Hence, **P3** is a non-concave optimization problem. Thus, solving **P3** is a challenging task. In the following we provide two approaches to solve **P3**. The first approach finds the global optimal solution by using the monotonic optimization theory at the expense of high complexity. The second approach utilizes the geometrical structure of the feasible set to find the global optimal solution with much lower complexity, and it is denoted as GALEN. Moreover, GALEN provides a closed form expression for the optimal solution which make it very useful for resource allocation.

III. OPTIMAL POWER ALLOCATION BY MONOTONIC OPTIMIZATION

In this section, we focus on finding the optimal solution of **P3**, the equivalent problem of **P1**, with the assumption that the BS has perfect knowledge about the channel state information for both the cellular and the D2D users.

In general, globally solving a non-convex optimization problem can involve examining every point in the feasible set. Contrarily, monotonic optimization theory exploits the monotonicity property of the utility function and the constraints in the optimization problem in a much more efficient way but still with exponential complexity in the number of optimization variables. The key idea behind monotonic optimization theory is to search for the global solution on the outer boundary of the feasible set instead of exploring the complete feasible set of the problem. Thus, the usage of monotonic optimization theory is limited to the problems which have certain properties. In particular, the monotonic optimization tool can solve the general problem $\max_{x \in \mathcal{G} \cap \mathcal{H}} f(x)$ providing that the following three properties hold true [14, Chapter I].

- $f(x)$ is an increasing function;
- \mathcal{G} is a normal set;
- \mathcal{H} is a co-normal set.

A function $f : \mathbb{R}^n \mapsto \mathbb{R}$ is called an increasing function if for any two vectors $\mathbf{x} \in \mathbb{R}^N$ and $\mathbf{y} \in \mathbb{R}^N$ we have $f(x) \preceq f(y)$ when $0 \preceq x \preceq y$ ². A set $\mathcal{G} \subset \mathbb{R}^n$ is normal (co-normal) set, if for any point $x \in \mathcal{G}$, all other points x' such that $x' \preceq x$ ($x' \geq x$) are also in the set \mathcal{G} . Based on the above requirements **MO** appears to be non-applicable to **P3** (Since Q_j is non-increasing with \mathbf{p}_j). In the following we show how to transform **P3** into an **MO** problem.

It is first straightforward to claim that $\Gamma_{d1}^j(\mathbf{p}_j)$, $\Gamma_{d2}^j(\mathbf{p}_j)$, and $\Gamma_{bs}^j(\mathbf{p}_j)$ are always strictly positive. Now let $\Gamma_j = (\Gamma_{d1}^j, \Gamma_{d2}^j, \Gamma_{bs}^j)$ be the achieved SINR vector for all links, it is clear that the function $Q(\Gamma_j)$ is an increasing function with Γ_j . Thus, the optimization problem defined in (10) has a hidden monotonicity structure which can be extracted by using the reformulation of [15, Section III]. The latter is given below:

$$\mathbf{P4} : \mathbf{z}_j^* = \operatorname{argmax}_{\mathbf{z}_j} Q_j(\mathbf{z}_j) = (1 + z_{d1}^j)(1 + z_{d2}^j)$$

$$\text{s.t. } \mathbf{z}_j \in \mathcal{S} = \mathcal{S}_n \cap \mathcal{S}_c$$

$$\mathcal{S}_n = \{\mathbf{z}_j | \mathbf{z}_j \preceq \Gamma_j, \mathbf{p}_j \preceq \mathbf{p}_{\max}\} \quad (11)$$

$$\mathcal{S}_c = \{z_{bs}^j \geq \gamma_{\min}^j, z_{d1}^j \geq 0, z_{d2}^j \geq 0\} \quad (12)$$

wherein $\mathbf{z}_j = (z_{d1}^j, z_{d2}^j, z_{bs}^j)$ and $\mathbf{z}_j^* = (z_{d1}^{j,*}, z_{d2}^{j,*}, z_{bs}^{j,*})$. It is easily verified that the new objective function $Q_j(\mathbf{z}_j)$ is an increasing function with \mathbf{z}_j , and that \mathcal{S}_n and \mathcal{S}_c are respectively normal and co-normal sets. Hence **P4** is **MO** problem and it can be solved in exponential time using the outer polyblock approximation algorithm (OPA) described in [15] and reported in [14, Algorithm 3]. The OPA algorithm solves the rate maximization problem by constructing a sequence of shrinking polyblocks that eventually reaches the global optimal point.

Since the objective function of **P4** is increasing with \mathbf{z}_j , the optimal solution \mathbf{z}_j^* must occur at a place where $\mathbf{z}_j = \Gamma_j$. Accordingly, the optimal solution of (10) denoted by \mathbf{p}_j^* can be recovered by solving the following linear equations system:

$$\begin{cases} P_{d1}^j \eta z_{d1}^{j,*} - P_{d2}^j g_d^j + P_c^j h_{c,d1}^j z_{d1}^{j,*} + z_{d1}^{j,*} N_0 = 0, \\ -P_{d1}^j g_d^j + P_{d2}^j \eta z_{d2}^{j,*} + P_c^j h_{c,d2}^j z_{d2}^{j,*} + z_{d2}^{j,*} N_0 = 0, \\ P_{d1}^j h_{d1,bs}^j z_{d3}^{j,*} + P_{d2}^j h_{d2,bs}^j z_{d3}^{j,*} - P_c^j g_{c,bs}^j + z_{d3}^{j,*} N_0 = 0. \end{cases} \quad (13)$$

As a result, solving **P4** for all $j \in \{1, 2, \dots, M\}$ yields to the optimal solution of **P3**. Due to the exponential complexity of OPA, in the next section, we develop an analytical framework to compute the global optimal point with low complexity.

IV. GALEN'S FRAMEWORK

Despite the interest of **MO** optimization theory, the latter converges to the optimal solution at the expense of exponential complexity. In this section, we provide a mathematical framework named GALEN which finds the optimal solution of **P2** in an efficient way, by analyzing the geometric structure of the feasible set Φ .

²In this paper we use $\mathbf{x} \preceq \mathbf{y}$ to denote that the vector $\mathbf{y} \in \mathbb{R}^N$ is greater than or equal to $\mathbf{x} \in \mathbb{R}^N$ in a component-wise manner.

A. Geometric representation of Φ

The feasible set Φ of each couple $(D2D_j, CU_j)$ can be rewritten as follows:

$$\Phi = \{P_c^j g_{c,bs}^j - \gamma_{\min}^j (P_{d1}^j h_{d1,bs}^j + P_{d2}^j h_{d2,bs}^j + N_0) \geq 0 \quad (14)$$

$$0 \leq P_i^j \leq P_{\max}^i, i \in \{d1, d2, c\}\} \quad (15)$$

Equations (14) and (15) respectively represent the QoS constraint of CU_j and the power constraints of the couple $(D2D_j, CU_j)$. Denote by \mathcal{P}_c the equality case of (14), i.e., the QoS plane. Moreover, let \mathcal{P}_i^{\max} (\mathcal{P}_i^0) be the maximum (minimum) power planes, i.e., $P_i^j = P_{\max}^i$ ($P_i^j = 0$) where $i \in \{c, d1, d2\}$. Hence, in the three dimensional space $(P_{d1}^j, P_{d2}^j, P_c^j)$, Φ can be represented as the intersection of \mathcal{P}_c with \mathcal{P}_i^0 and \mathcal{P}_i^{\max} , where $i = \{c, d1, d2\}$.

It can be observed that \mathcal{P}_i^{\max} (\mathcal{P}_i^0) with $i \in \{d1, d2, c\}$, are fixed in the 3D-space and they form a cuboid shape as shown in Fig.2a-2e. However, the plane \mathcal{P}_c varies according to the channel situation of $(D2D_j, CU_j)$ and the required rate of CU_j . Thus, Φ may have different possible shapes as shown in Fig.2a-2e.

Fig. 2. The possible shapes of the feasible set Φ . (\mathcal{P}_c \square)

Fig.2a-2c shows the cases where \mathcal{P}_c has intersection with two maximum power planes and two minimum power planes. Fig.2b shows the case where \mathcal{P}_c intersects all the maximum and the minimum power planes, while Fig.2e shows the case where \mathcal{P}_c intersects the plane \mathcal{P}_c^{\max} , \mathcal{P}_{d1}^0 and \mathcal{P}_{d2}^0 . The thick lines in the above figures represent the intersection lines of \mathcal{P}_c with the maximum power planes. The corner of these lines

are denoted as v_i with $i = \{1, 2, \dots, 7\}$. Moreover, we define the follows $v_1 \triangleq \mathcal{P}_c \cap \mathcal{P}_{d1}^{\max} \cap \mathcal{P}_{d2}^0$; $v_2 \triangleq \mathcal{P}_c \cap \mathcal{P}_{d2}^{\max} \cap \mathcal{P}_{d1}^0$; $v_3 \triangleq \mathcal{P}_c \cap \mathcal{P}_{d1}^{\max} \cap \mathcal{P}_{d2}^{\max}$; $v_4 \triangleq \mathcal{P}_c \cap \mathcal{P}_{d2}^{\max} \cap \mathcal{P}_c^{\max}$; $v_5 \triangleq \mathcal{P}_c \cap \mathcal{P}_c^{\max} \cap \mathcal{P}_{d2}^0$; $v_6 \triangleq \mathcal{P}_c \cap \mathcal{P}_{d1}^{\max} \cap \mathcal{P}_c^{\max}$; and $v_7 \triangleq \mathcal{P}_c \cap \mathcal{P}_c^{\max} \cap \mathcal{P}_{d1}^0$. Thus the coordinate of these vertices can be expressed as follows:

$$v_1 = (P_{\max}^{d1}; 0; (P_{\max}^{d1} h_{d1,bs}^j + N_0) \gamma_{\min}^j / g_{c,bs}^j)$$

$$v_2 = (0; P_{\max}^{d2}; (P_{\max}^{d2} h_{d2,bs}^j + N_0) \gamma_{\min}^j / g_{c,bs}^j)$$

$$v_3 = (P_{\max}^{d1}; P_{\max}^{d2}; (P_{\max}^{d1} h_{d1,bs}^j + P_{\max}^{d2} h_{d2,bs}^j + N_0) \gamma_{\min}^j / g_{c,bs}^j)$$

$$v_4 = ((P_{\max}^{c} g_{c,bs}^j / \gamma_{\min}^j - P_{\max}^{d2} h_{d2,bs}^j - N_0) / h_{d1,bs}^j; P_{\max}^{d2}; P_{\max}^c)$$

$$v_5 = ((P_{\max}^c g_{c,bs}^j / \gamma_{\min}^j - N_0) / h_{d1,bs}^j; 0; P_{\max}^c)$$

$$v_6 = (P_{\max}^{d1}; (P_{\max}^c g_{c,bs}^j / \gamma_{\min}^j - P_{\max}^{d1} h_{d1,bs}^j - N_0) / h_{d2,bs}^j; P_{\max}^c)$$

$$v_7 = (0; (P_{\max}^c g_{c,bs}^j / \gamma_{\min}^j - N_0) / h_{d2,bs}^j; P_{\max}^c)$$

B. Optimal power allocation

Denote by $\Omega = \{\overline{v_1 v_3}; \overline{v_2 v_3}; \overline{v_4 v_5}; \overline{v_6 v_7}; \overline{v_4 v_6}; \overline{v_5 v_7}\}$ the set of the intersection lines between \mathcal{P}_c and the maximum power planes. The following lemma shows that the optima can be searched only in Ω instead of Φ . Here it is worthy mentioning that Ω is an exclusive set, i.e., not all its members occurs at the same time as shown in Fig.2a-2e.

Lemma 1. The optimal power vector \mathbf{p}_j^* has at least one power bounded by the maximum power constraint and it lies on the QoS plane \mathcal{P}_c .

Proof: For any scaling parameter $\mu > 1$ and a power vector $\mathbf{p}_j = (P_{d1}^j, P_{d2}^j, P_c^j) \in \Phi$ we have:

$$Q_j(\mu \mathbf{p}_j) = \left[\left(1 + \frac{P_{d2} g_d}{P_c g_{c,d1} + \eta P_{d1} + \sigma_N^2 / \mu} \right) \times \right. \quad (16)$$

$$\left. \left(1 + \frac{P_{d1} g_d}{P_c g_{c,d2} + \eta P_{d2} + \sigma_N^2 / \mu} \right) \right] > Q_j(\mathbf{p}_j)$$

The power constraints defined in (15) imply that the maximum μP_i^j is P_{\max}^i , $i \in \{d1, d2, c\}$ (due to inequality in (16)). Hence, the optimal point \mathbf{p}_j^* can be achieved only if at least one user is transmitting with the maximum allowed power.

On the other hand, since Q_j monotonically decreases with P_c^j , the maximum R_{fd}^j occurs when CU_j transmits with the minimum required power. Thus, \mathbf{p}_j^* must reside on the plane \mathcal{P}_c . As a result, the optimal points must reside in Ω . ■

Lemma 1 reduces the feasible set Φ to Ω , and thus the optimal point can be obtained by solving the power allocation problem defined in (10) over the different points of Ω .

Being on $\overline{v_1 v_3}$ (see Fig.2a) or $\overline{v_1 v_6}$ (see Fig.2b and Fig.2c) implies that $P_{d1}^j = P_{\max}^{d1}$ and $P_c^j = (P_{\max}^{d1} h_{d1,bs}^j + P_{d2}^j h_{d2,bs}^j + N_0) \gamma_{\min}^j / g_{c,bs}^j$. In such case, the objective function of (10) reduces to

$$Q_j(\mathbf{p}_j) = \left(1 + \frac{P_{d2}^j}{P_{d2}^j a_0 + a_1} \right) \left(1 + \frac{P_{\max}^{d1}}{P_{d2}^j a_2 + a_3} \right), \quad (17)$$

where the constant coefficients in the above equation are defined as

$$\begin{aligned} a_0 &= \frac{\gamma_{\min}^j h_{d2,bs}^j h_{c,d1}^j}{g_{c,bs}^j g_d^j}; a_2 = \frac{\eta g_{c,bs}^j + \gamma_{\min}^j h_{d2,bs}^j h_{c,d2}^j}{g_{c,bs}^j g_d^j} \\ a_1 &= \frac{P_{\max}^{d1}}{g_d^j} \left(\eta + \frac{\gamma_{\min}^j h_{d1,bs}^j h_{c,d1}^j}{g_{c,bs}^j} \right) + \frac{N_0}{g_d^j} \left(1 + \frac{\gamma_{\min}^j h_{c,d1}^j}{g_{c,bs}^j} \right) \\ a_3 &= \frac{\gamma_{\min}^j P_{\max}^{d1} h_{d1,bs}^j h_{c,d2}^j}{g_{c,bs}^j g_d^j} + \frac{N_0}{g_d^j} \left(1 + \frac{\gamma_{\min}^j h_{c,d2}^j}{g_{c,bs}^j} \right). \end{aligned}$$

Taking the first derivative of (17) w.r.t P_{d2}^j leads to the following:

$$\frac{\partial(17)}{\partial P_{d2}^j} = \frac{A_1 P_{d2}^{j2} + 2B_1 P_{d2}^j + C_1}{D_1} \quad (18)$$

where the constants A , B , C and D are given as follows:

$$\begin{aligned} A_1 &= (a_2^2 a_1 - P_{\max}^{d1} a_0 a_2 (a_0 + 1)); \\ B_1 &= -(P_{\max}^{d1} a_0 - a_3) a_2 a_1; C_1 = P_{\max}^{d1} (a_1 a_3 - a_1^2 a_2) + a_1 a_3^2; \\ D_1 &= (P_{d2}^j a_0 + a_1)^2 (P_{d2}^j a_2 + a_3)^2. \end{aligned}$$

Since D_1 is always positive, a possible optima of (17) would be the solution of $A_1 P_{d2}^{j2} + 2B_1 P_{d2}^j + C_1$. Denote such optima point as e_1 , the coordinates of e_1 are given by:

$$e_1 = \left(\begin{array}{c} P_{\max}^{d1}; \frac{1}{A_1} \left(-B_2 \pm \sqrt{B_1^2 - A_1 C_1} \right); \\ \gamma_{\min}^j \left(P_{\max}^{d1} h_{d1,bs}^j + P_{d2,e_1}^j h_{d2,bs}^j + N_0 \right) / g_{c,bs}^j \end{array} \right), \quad (19)$$

with P_{d2,e_1}^j being the P_{d2}^j abscissa of e_1 .

The above solution does not always provide a global maxima of (17), since there is no guarantee that the second derivative is always negative. Moreover, e_1 may not be always a feasible point (since it may lie outside $\overline{v_1 v_3}$ or $\overline{v_1 v_6}$, or it might be an imaginary point). Accordingly, the global maxima of (17) would be either one of the corner points of the line $\overline{v_1 v_3}$ ($v_1 v_6$), i.e., v_1 or v_3 (v_6), or the extreme point e_1 (if e_1 is feasible).

In the same manner, the optimal point of (10) on the line $\overline{v_2 v_3}$ as in Fig.2a (or $\overline{v_2 v_4}$ as in Fig.2b and Fig.2d) is either one of the corner points v_2 or v_3 (v_4) or an extreme point e_2 which lies on $\overline{v_2 v_3}$ ($\overline{v_2 v_4}$) and has the following coordinate:

$$e_2 = \left(\begin{array}{c} \frac{1}{A_2} \left(-B_2 \pm \sqrt{B_2^2 - A_2 C_2} \right); \\ P_{\max}^{d2}; \gamma_{\min}^j \left(P_{d1,e_2}^j h_{d1,bs}^j + P_{\max}^{d2} h_{d2,bs}^j + N_0 \right) / g_{c,bs}^j \end{array} \right), \quad (20)$$

where the constants A_2 , B_2 , and C_2 are given by

$$\begin{aligned} A_2 &= (b_2^2 b_1 - P_{\max}^{d2} b_0 b_2 (b_0 + 1)); \\ B_2 &= (b_3 - P_{\max}^{d2} b_0) b_2 b_1; C_2 = P_{\max}^{d1} (b_1 b_3 - b_1^2 b_2) + b_1 b_3^2, \end{aligned}$$

and the constant coefficients b_0 , b_1 , b_2 , and b_3 are given by

$$\begin{aligned} b_0 &= \frac{\gamma_{\min}^j h_{d1,bs}^j h_{c,d2}^j}{g_{c,bs}^j g_d^j}; b_2 = \frac{\eta g_{c,bs}^j + \gamma_{\min}^j h_{d1,bs}^j h_{c,d1}^j}{g_{c,bs}^j g_d^j} \\ b_1 &= \frac{P_{\max}^{d2}}{g_d^j} \left(\eta + \frac{\gamma_{\min}^j h_{d2,bs}^j h_{c,d2}^j}{g_{c,bs}^j} \right) + \frac{N_0}{g_d^j} \left(1 + \frac{\gamma_{\min}^j h_{c,d2}^j}{g_{c,bs}^j} \right) \\ b_3 &= \frac{\gamma_{\min}^j P_{\max}^{d2} h_{d2,bs}^j h_{c,d1}^j}{g_{c,bs}^j g_d^j} + \frac{N_0}{g_d^j} \left(1 + \frac{\gamma_{\min}^j h_{c,d1}^j}{g_{c,bs}^j} \right). \end{aligned}$$

Similarly, the optimal point of (10) on the line $\overline{v_6 v_4}$ as in Fig.2d (or $\overline{v_5 v_7}$ as in Fig.2e) is either one of the corner points v_4 or v_6 (v_5 or v_7) or an extreme point e_3 which lies on $\overline{v_6 v_4}$ ($\overline{v_5 v_7}$) and has the following coordinate

$$e_3 = \left(\begin{array}{c} \frac{1}{A_3} \left(-B_3 \pm \sqrt{B_3^2 - A_3 C_3} \right); \\ \frac{1}{h_{d2,bs}^j} \left(\frac{P_{\max}^{c} g_{c,bs}^j}{\gamma_{\min}^j} - N_0 - P_{d1,e_3}^j h_{d1,bs}^j \right); P_{\max}^c \end{array} \right), \quad (21)$$

where the constants A_3 , B_3 , and C_3 are given by

$$\begin{aligned} A_3 &= \eta c_3 (\eta - c_2) - c_4 (c_4 - 1) (c_0 c_2 + c_1 \eta); \\ B_3 &= ((c_2 c_4 - c_2 + \eta) c_0 + \eta c_1 c_4) c_3; \\ C_3 &= c_3 (c_0 (c_0 + c_1) - (c_0 c_2 + c_1 \eta) c_3); \end{aligned}$$

and the constant coefficients c_0 , c_1 , c_2 , and c_3 are given by

$$\begin{aligned} c_0 &= \frac{1}{g_d^j} (P_{\max}^c g_{c,d1} + N_0); c_1 = \frac{P_{\max}^c g_{c,bs}^j}{\gamma_{\min}^j h_{d2,bs}^j} - \frac{N_0}{h_{d2,bs}^j}; \\ c_2 &= \frac{h_{d1,bs}^j}{h_{d2,bs}^j}; c_4 = \frac{\eta h_{d1,bs}^j}{h_{d2,bs}^j g_d^j}; \\ c_3 &= \frac{P_{\max}^c}{g_d^j} \left(g_{c,d2} + \frac{\eta g_{c,bs}^j}{\gamma_{\min}^j h_{d2,bs}^j} \right) + \frac{N_0}{g_d^j} \left(1 - \frac{\eta}{h_{d2,bs}^j} \right). \end{aligned}$$

Accordingly, the optimal point would be the point which gives higher rate. The following Theorem summarizes all the previous discussion.

Theorem 1. *The optimal power vector \mathbf{p}_j^* can be searched only in the set \mathcal{P}_{opt} defined as*

$$\mathcal{P}_{opt} = \{v_1, v_2, v_3, v_4, v_5, v_6, v_7, e_1, e_2, e_3\} \quad (22)$$

Here we should emphasize that Theorem 1 reduces the feasible set from a three dimensional shape to a set of points with known coordinates. Hence, with GALEN the global optimal point can be obtained in one iteration on contrary to the MO algorithm which requires a high number of iterations. Moreover, GALEN provides a closed form expression of the optimal solution.

V. NUMERICAL RESULTS

In this section we aim to find the ultimate performance of a FD-D2D enabled cellular network. To that end, we consider a single cell network with radius R and M CUEs and D2D pairs. The CUs are equally sharing the uplink bandwidth and they are uniformly distributed in the cell. Moreover, each $D2D_j$ pair is uniformly distributed within a randomly located cluster with radius r , and is sharing the same resource of CU_j . All the simulation parameters are summarized in Table I.

TABLE I
SIMULATION PARAMETERS

Cell radius (R)	500m
Cluster radius(r)	10m, 20m, 40m, 80m
Number of CUs and D2D pairs (M)	15
Bandwidth of CU_j (B_j)	180KHz
Noise power (N_0)	-114 dBm
Path-loss exponent (α)	4
Maximum power of CUE and D2D users	24 dBm
SINR requirement for CUs (γ_{\min}^j)	uniform distributed in [0,25] dB
SI cancellation factor (η)	-100,-90,.....-50 dB
Multiple-path fading	Exponential distribution with $l_{ij}^{-\alpha}$ mean

A. GALEN VS MO

In this subsection we aim to validate GALEN by comparing its results with the well known monotonic optimization framework. Fig. 3 shows the variation of the D2D rate w.r.t the SI cancellation factor and the D2D cluster radius. Moreover, it compares the proposed power allocation GALEN with the MO method for different cluster radius and different SI cancellation factors. In this figure we consider 500 realizations each with $M = 15$ CUEs and $M = 15$ D2D pairs. At Each iteration we averaged the results of all the couples ($D2D_j, CU_j$) and finally we averaged the results over all realizations. As it can be seen, the curves perfectly match in all cases. Moreover, Fig. 3 clearly shows that as the cluster radius r increases, the average rate decreases. As expected, we can see that the average rate increases as the SI factor decreases.

Moreover, to highlight the importance of GALEN, we show in Fig. 4 the complexity of MO in terms of the required number of iterations to achieve the global optimality. As it can be seen, the MO theory requires 10^4 to achieve the optimal point. However, from Theorem 2, we know that GALEN obtains the optimal solution by searching a set of ten points. This low complexity feature makes GALEN a perfect choice for power allocation. Moreover, it makes the analysis of a FD-D2D network easier. Fig. 4 also shows that the number of iterations declines with the increasing of the cluster radius. This is because when r increases the average number of admitted D2D pairs decreases.

B. FD-D2D or HD-D2D

Here we aim to investigate the performance of the FD-D2D communication, and see if it always outperforms the HD-D2D mode. To that end, and for fair comparison with FD, we assume that in the HD mode the D2D users in each D2D pair are equally sharing the bandwidth B_j . Therefore, the received SINR at the BS will remain the same as in (1). However, the received SINR at D_1^j and D_2^j will no longer contain the SI component (i.e. η component). Accordingly, denote by $\Gamma_{hd,d1}^j$ and $\Gamma_{hd,d2}^j$ the received SINR at the D2D devices in the HD mode, we have $\Gamma_{hd,d1}^j = \Gamma_{d1}^j|_{\eta=0}$ and $\Gamma_{hd,d2}^j = \Gamma_{d2}^j|_{\eta=0}$. Consequently, the HD D2D rate (R_{hd}^j) becomes $R_{hd}^j = \frac{1}{2}R_{hd}^j|_{\eta=0}$. Based on that, by setting $\eta = 0$, both GALEN and MO can be used to derive the global optimal

Fig. 3. Comparison of FD-D2D rate obtained from GALEN and from the MO theory.

Fig. 4. The average number of iterations in the MO algorithm.

solution of the rate maximization problem when the D2D users are operating in HD mode.

In Fig.5 we compare the FD-D2D performance with the HD-D2D in terms of the average D2D rate. In particular, Fig. 5 shows the variation of the D2D rate w.r.t the SI cancellation factor and for different D2D cluster radius. As it can be seen, at low self interference cancellation in the FD mode, the HD mode outperforms FD. In addition when the separation between the D2D users increases the FD mode needs higher SI cancellation to outperform the HD mode. As a result, the FD gain mainly appears when the D2D users are close to each other and they have high SI cancellation capability. Hence, to achieve the maximum gain from the D2D technology, a mode selection step must always be taken into consideration when allocating the resources for the users. The latter is out of scope of the paper and will be elaborated in the future.

VI. CONCLUSION

This paper proposed two approaches to globally solve the power allocation problem of a FD-D2D network. The first one is based on the MO theory to the detriment of high complexity, while the latter, denoted GALEN, is a geometric-based approach with very low complexity. The simulation results have validated the simplified GALEN approach and have shown its low complexity feature. Moreover, simulation results have shown that the HD-D2D might outperform the FD-D2D in some situations. As a future work, the resource allocation

Fig. 5. Comparison of the FD-D2D rate and the HD-D2D rate.

which contains mode selection and channel assignment of a FD-D2D network will be considered. In addition, it might be interesting to analyze the maximization problem of the global cell rate, i.e., the rate of both D2D and the cellular users.

ACKNOWLEDGEMENT

This work was partially funded through French National Research Agency (ANR) project WONG5 with grant agreement code: ANR-15-CE25-0005603. A part of this work was also carried out thanks to the STSM grant of COST Action CA15104 (IRACON) and CNRS (GdR-ISIS).
